

# TamaGo

## Bare metal Go

Secure embedded unikernels  
with drastically reduced attack surface

# \$ whoami

Information Security Engineer and Researcher

Co-Founder: **INVERSE PATH** (2005 - 2017)

Head of Hardware Security:  

Head of Security Engineering: 

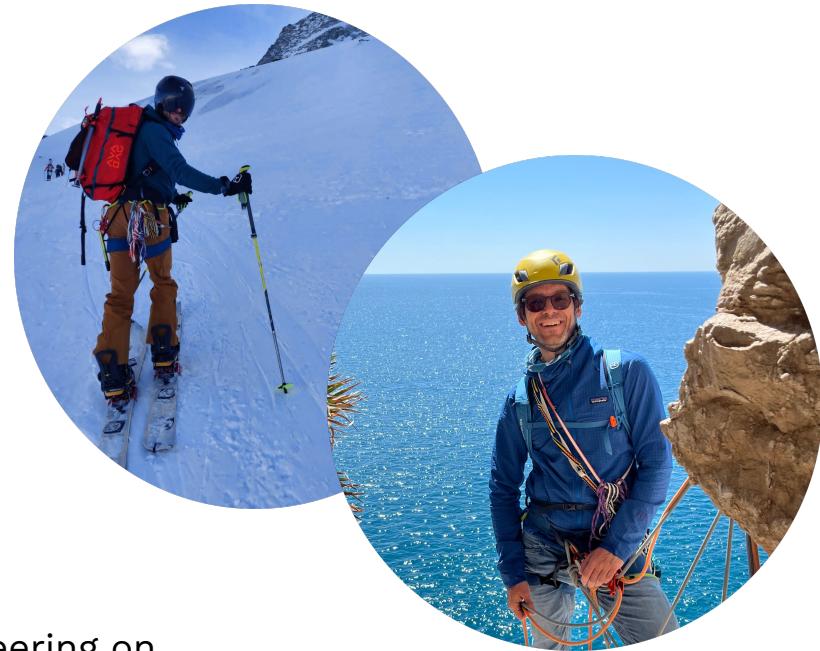

Co-creator, USB armory: 

Speaker at too many conferences...

Background focused on security auditing and engineering on safety critical systems in the automotive, avionics, industrial domains.

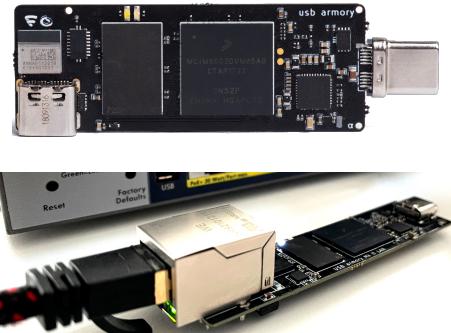

Now also hacking compilers and runtimes...

# Andrea Barisani

# Motivation: USB armory firmware

---

The USB armory is a tiny, but powerful, embedded platform for personal security applications.

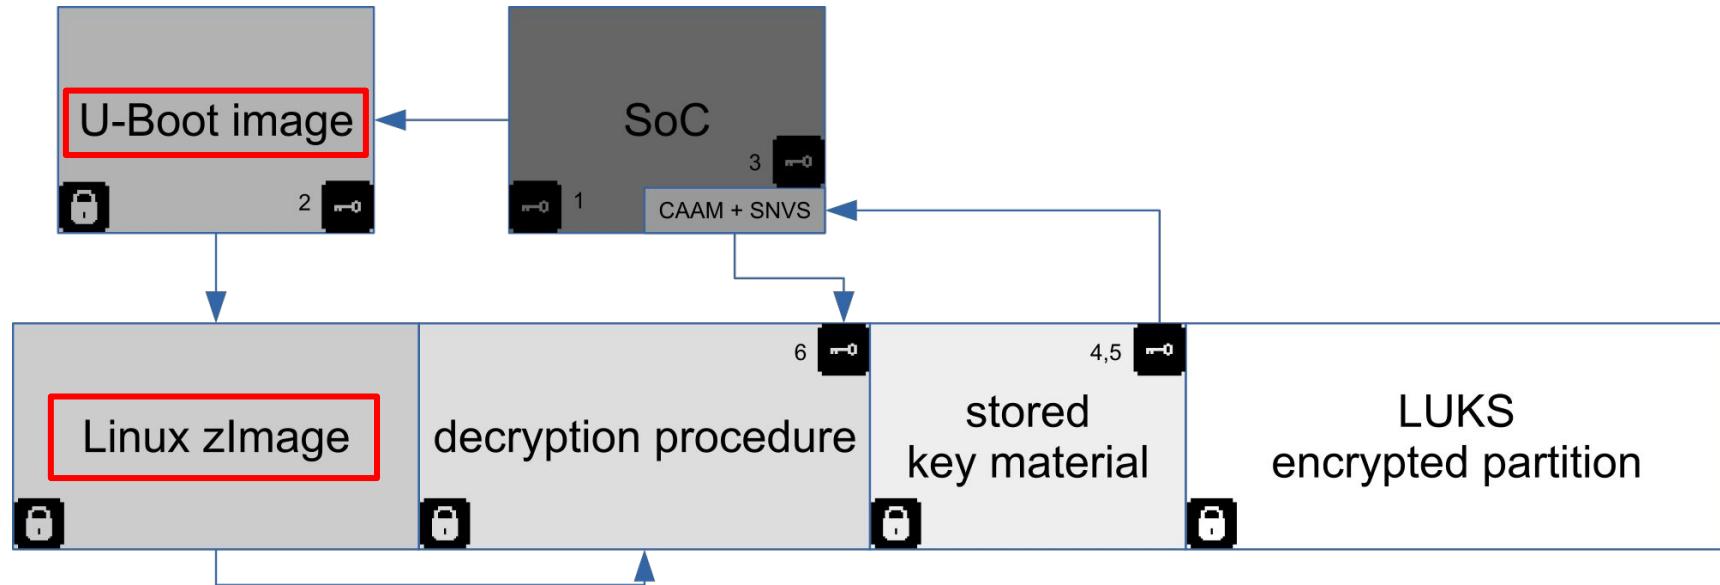

Designed to fit in a pocket, laptops, PCs, server and networks (LAN model with PoE).

The USB armory targets the following primary applications:

- Encrypted storage solutions
- Hardware Security Module (HSM)
- Enhanced smart cards
- Electronic vaults (e.g. cryptocurrency wallets) and key escrow services
- Authentication, provisioning, licensing tokens
- USB firewall

# Reducing the attack surface

Typical secure booted firmware with authentication and confidentiality on an NXP i.M6UL.

# Motivation

---

In an ideal world **you should be free to choose the programming language you prefer.**

In an ideal world **all compilers would generate machine code with the same efficiency.**

However in real world lower specs heavily dictate language choices:

Microcontroller (MCU) firmware == unsafe<sup>1</sup> low level languages (C)

Examples:      cryptographic tokens, cryptocurrency wallets, hardware data diodes,  
lower specs IoT and “smart” appliances.

---

<sup>1</sup> **Pro tip:** certification does not matter.

# Motivation

---

In an ideal world using **higher level languages should not entail complex dependencies**.

In an ideal world **higher level languages should reduce complexity**.

**Complexity should be reduced for the entire environment**, not just being shifted away.

However in real world higher specs heavily dictate OS requirements:

System-on-Chip (SoC) firmware == complex OS + safe (or unsafe<sup>1</sup>) languages

Examples: TEE applets, infotainment units, avionics gateways, home routers, higher specs IoT and “smart” appliances.

---

<sup>1</sup> Privileged C-based apps running under Linux to “parse stuff” are very common, like your car infotainment/parking ECU.

# Killing C

---

When security matters software and hardware optimizations matter less.

This means that less constrained hardware (e.g. SoCs in favor of MCUs) and higher level code are perfectly acceptable.

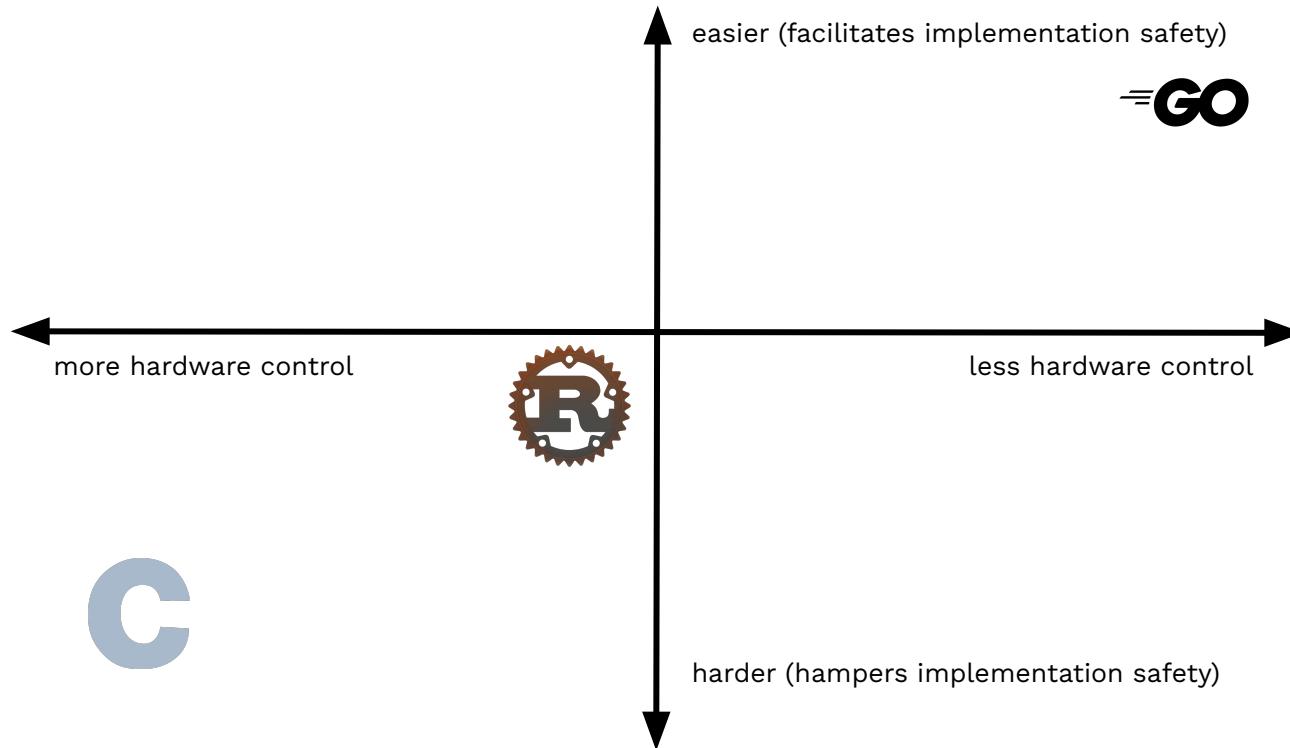

However high level programming typically entails several layers (e.g. OS, libraries) to serve runtime execution.

TamaGo spawns from the desire of **reducing the attack surface** of embedded systems firmware by **removing any runtime dependency on C code and inherently complex Operating Systems**.

In other words we want to **avoid shifting complexity around** and run a **higher level language**, such as Go in our effort, **directly on the bare metal**.

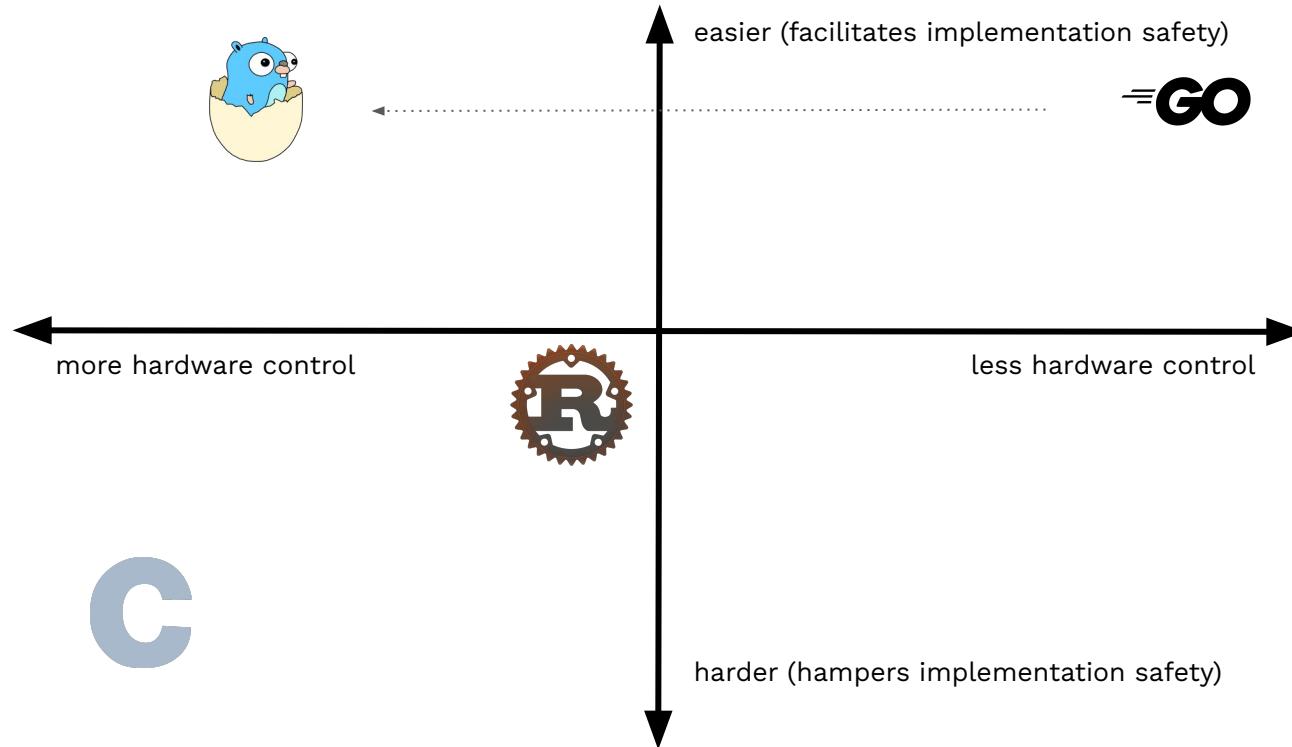

# Speed vs Safety

**Disclaimer:** chart presented for discussion and not to claim that language X is better than language Y, also scale is subjective.

# Speed vs Safety

**Disclaimer:** chart presented for discussion and not to claim that language X is better than language Y, also scale is subjective.

# Unikernels / library OS

Unikernels<sup>1</sup> are a single address space image to execute a “library operating system”, typically running under bare metal.

The focus is reducing the attack surface, carrying only strictly necessary code.

“True” unikernels are mostly unicorns, as a good chunk of available ones do not fit in this category and represent “fat” unikernels running under hypervisors and/or other (mini) OSes. And just shift around complexity (e.g. the app is PID 1).

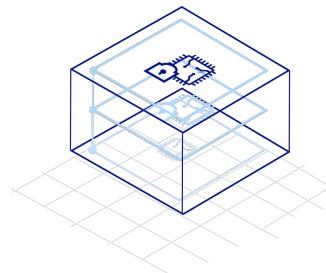

Apart from some exceptions there is always still a lot of C/dependencies involved in the underlying OS, drivers or hypervisor.

## Running or importing \*BSD kernels

Rump kernels (NetBSD based)  
OSv (re-uses code from FreeBSD)

## Running under hypervisor and 3rd party kernel

MirageOS (Solo5)  
ClickOS (MiniOS)

## Running under hypervisor

Nanos (Xen/KVM/Qemu) HalVM (Haskell, Xen)  
LING (Erlang, Xen) RustyHermit (KVM)

## Bare metal

GRISP (Erlang)  
IncludeOS

<sup>1</sup> <https://en.wikipedia.org/wiki/Unikernel>

# Unikernel security

---

From a security standpoint leveraging on Unikernels (whatever the kind) to run multiple applications or an individual C applications is not ideal<sup>1</sup>.

Having an industry standard OS is necessary to support required security measures which otherwise are not present or rather primitive on most Unikernels.

Again, we want to **kill C** from the entire environment while keeping code efficiency, developing drivers having “only” to worry about interpreting reference manuals.

Unlike most unikernel projects focus started on **small embedded systems**, later focus **expanded** to TEEs, KVMs and bootloader applications.

We chose **Go** for its shallow learning curve, productivity, strong cryptographic library and standard library.

Languages like Rust have already proven they role in bare metal world, Go on the other hand needs to ... and it really can!

---

<sup>1</sup> <https://research.nccgroup.com/2019/02/04/assessing-unikernel-security/>

# TamaGo in a nutshell

- A **minimally<sup>1</sup>** patched Go distribution to enable `GOOS=tamago` support, which provides freestanding execution on `GOARCH={ amd64 | arm | arm64 | riscv64 }bare metal`.
- A set of packages<sup>2</sup> for platform support, including hardware initialization (e.g. boot).

## AMD64

cloud_hypervisor/vm	Cloud Hypervisor
firecracker/microvm	Firecracker
qemu/microvm	QEMU microvm
google/gcp	Google Compute Engine
uefi/x64	UEFI

## ARM

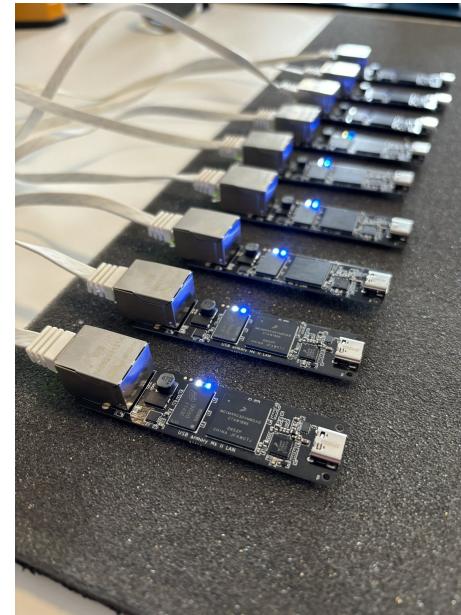

nxp/mx6ullevk	NXP MCIMX6ULL-EVK
raspberrypi/pi1	Pi 1
raspberrypi/pi2	Pi 2
raspberrypi/pizero	Pi Zero
usbarmory/mk2	USB armory Mk II (USB+LAN)

## ARM64

nxp/imx8mpevk	NXP 8MPLUSLPD4-EVK
---------------	--------------------

## RISCV64

qemu/sifive_u	QEMU SiFive HiFive Unleashed
---------------	------------------------------

<sup>1</sup> <https://github.com/usbarmory/tamago-go>

<sup>2</sup> <https://github.com/usbarmory/tamago>

# Similar efforts

---

## Past/existing efforts

(all these projects greatly supported us in proving feasibility and identify TamaGo unique approach, diversity is good)

Biscuit (inactive) - <https://github.com/mit-pdos/biscuit>

Go kernel for non-Go software underneath, larger scope, needs two C bootloaders,  
hijacks GOOS=linux, only for GOARCH=amd64, redo memory allocation and threading.

G.E.R.T (inactive) - <https://github.com/ycoroneos/G.E.R.T>

ARM adaptation of Biscuit but without non-Go software support, needs two C bootloaders,  
hijacks GOOS=linux for GOARCH=arm, redo memory allocation and threading.

AtmanOS (inactive) - <https://github.com/atmanos>

Similar to TamaGo but targets the Xen hypervisor, adds GOOS=atman but with limited runtime support.

TinyGo (active) - <https://github.com/tinygo-org>

LLVM based compiler (not original one) aimed at MCUs and minimal footprint, does not  
support the entire runtime and Go language support differs from standard Go.

Embedded Go (active) - <https://github.com/embeddedgo>

Similar to TamaGo but targets ARMv7-M/ARMv8-M (w/ Thumb2) adding new support for it,  
as not native to Go. Adds GOOS=noos GOARCH=thumb .

Egg OS (inactive) - <https://github.com/icexin/eggos>

Targets x86, uses native compiler and wraps GOOS=linux syscalls back to Go.

# Enabling trust

---

TamaGo not only proves that it is possible to have a bare metal Go runtime, but does so with **clean and minimal modifications against the original Go distribution**<sup>2</sup>.

Much of the effort has been placed to understand whether Go bare metal support can be achieved without complex re-implementation of memory allocation, threading, ASM/C OS primitives that would “pollute” the Go runtime to unacceptable levels.

**Less is more. Complexity is the enemy of verifiability.**

The acceptance of this (and similar) efforts hinges on maintainability, ease of review, clarity, simplicity and **trust**.

- ★ Designed to achieve upstream inclusion and with commitment to always sync to latest Go release.
- ★ ~7000 LOC of changes against Go distribution with clean separation from other GOOS support.
- ★ Strong emphasis on code reuse from existing architectures of standard Go runtime, see [Internals](#)<sup>1</sup>.
- ★ Requires only one import (“library OS”) on the target Go application.
- ★ Supports unencumbered Go applications with native runtime and stdlib support.
- ★ In addition to the compiler, aims to provide a complete set of peripheral drivers for SoCs.

---

<sup>1</sup> <https://github.com/usbarmory/tamago/wiki/Internals>

<sup>2</sup> Which by the way is self-hosted and has reproducible builds.

# Go distribution modifications

**Glue code** - patches to adds GOOS=tamago to the list of supported architectures and required stubs for unsupported operations. All changes are benign (no logic/function):

```
// +build aix darwin dragonfly freebsd js,wasm linux nacl netbsd openbsd solaris tamago
```

**Re-used code** - patches that clone original Go runtime functionality from an existing architecture to (e.g. js, wasip1) GOOS=tamago, either unmodified or with minimal changes:

- plan9 memory allocation is re-used with 2 LOC changed (brk -> simple pointer)
- nacl in-memory filesystem is re-used (raw SD/MMC access implemented in imx6)
- net package is supported for networking through an external Socket function
- minimal architecture dependent code, unified {amd64, arm, arm64, riscv64} support

**New code** - basic syscall, memory layout and testing support:

```
rt0_tamago_{amd64,arm,arm64,riscv64}.s  
sys_tamago_{amd64,arm,arm64,riscv64}.s  
os_tamago_{amd64,arm,arm64,riscv64}.go
```

```
testing_tamago_{amd64,arm,arm64,riscv64}.go  
testing_tamago.go  
os_tamago.go
```

<https://github.com/golang/go/compare/go1.25.0...usbarmory:tamago1.25.0>

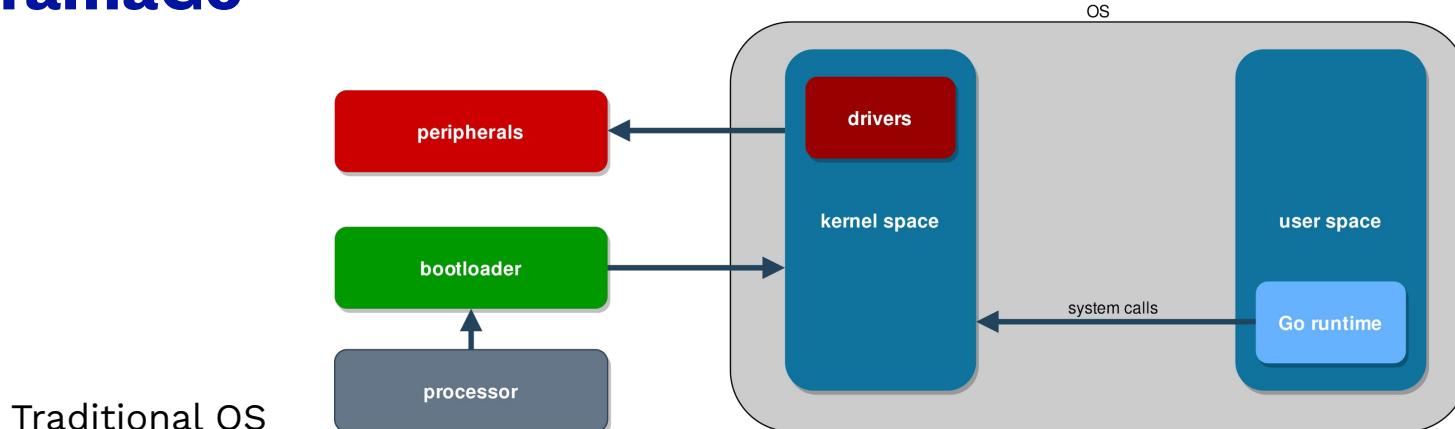

```
$ git diff go1.24.0 tamago1.24.0 --stat --stat-width "$(tput cols)" --color=always -- :(exclude)*tamago_test.go" | sort -t ' '| -n -k2 "$@"
```

# TamaGo

## TamaGo unikernel

# Go low level access

```
func (hw *BEE) Init() {
    hw.mu.Lock()
    defer hw.mu.Unlock()

    hw.ctrl = hw.Base + BEE_CTRL
    hw.key = hw.Base + BEE_AES_KEY0_W0

    reg.Set(hw.ctrl, CTRL_CLK_EN)          // enable clock
    reg.Set(hw.ctrl, CTRL_SFTRST_N)        // disable reset
    reg.Clear(hw.ctrl, CTRL_BEE_ENABLE)    // disable
}

func (hw *BEE) generateKey() (err error) {
    // avoid key exposure to external RAM
    key, err := dma.NewRegion(uint(hw.key), aes.BlockSize, false)

    if err != nil {
        return
    }

    addr, buf := key.Reserve(aes.BlockSize, 0)

    if n, err := rand.Read(buf); n != aes.BlockSize || err != nil {
        return errors.New("could not set random key")
    }

    if addr != uint(hw.key) {
        return errors.New("invalid key address")
    }

    return
}
```

Example: encrypted RAM init

Go's `unsafe` can be easily identified to spot areas that require care (e.g. pointer arithmetic), it is currently used only in register and DMA memory manipulation primitives.

There are overall only 3 occurrences of `unsafe` used in `dma` and `reg` packages.

Applications are never required to use any `unsafe` function.

No language changes mean that goroutines, channels, mutexes, interfaces can be used as usual.

## type Region

Region represents a memory region allocated for DMA purposes.

### func NewRegion

```
func NewRegion(addr uint, size int, unsafe bool) (r *Region, err error)
```

NewRegion initializes a memory region for DMA buffer allocation.

To avoid unforeseen consequences the caller must ensure that allocated regions do not overlap among themselves or with the global one (see Init()).

To allow allocation of DMA buffers within Go runtime memory the unsafe flag must be set.

### func (\*Region) Alloc

```
func (r *Region) Alloc(buf []byte, align int) (addr uint)
```

Alloc reserves a memory region for DMA purposes, copying over a buffer and returning its allocation address, with optional alignment. The region can be freed up with Free().

If the argument is a buffer previously created with Reserve(), then its address is returned without any re-allocation.

The optional alignment must be a power of 2 and word alignment is always enforced, 0 means 4 on 32-bit platforms and 8 on 64-bit ones.

## type BEE

BEE represents the Bus Encryption Engine instance.

### func (\*BEE) Enable

```
func (hw *BEE) Enable(region0 uint32, region1 uint32) (err error)
```

Enable activates the BEE using the argument memory regions, each can be up to AliasRegionSize (512 MB) in size.

After activation the regions are encrypted using AES CTR. On secure booted systems the internal OTPMK is used as key, otherwise a random one is generated and assigned.

After enabling, both regions should only be accessed through their respective aliased spaces (see AliasRegion0 and AliasRegion1) and only with caching enabled (see arm.ConfigureMMU).

### func (\*BEE) Init

```
func (hw *BEE) Init()
```

Init initializes the BEE module.

### func (\*BEE) Lock

```
func (hw *BEE) Lock()
```

Lock restricts BEE registers writing.

```
import (
    "github.com/usbarmory/tamago/soc/nxp/bee"
    "github.com/usbarmory/tamago/soc/nxp/imx6ul"
)

// Encrypt 1GB of external RAM, this is the maximum extent either
// covered by the BEE or available on USB armory Mk II boards.
region0 := uint32(imx6ul.MMDC_BASE)
region1 := region0 + bee.AliasRegionSize

imx6ul.BEE.Init()
defer imx6ul.BEE.Lock()

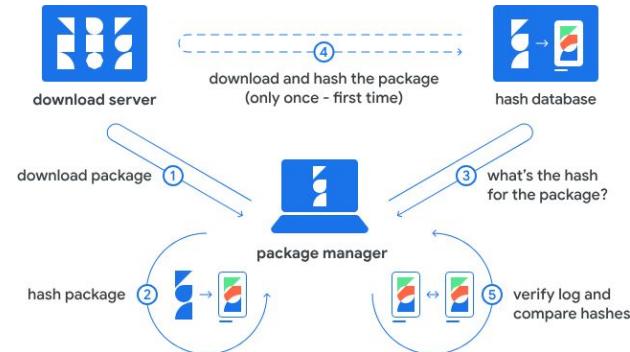

if err := imx6ul.BEE.Enable(region0, region1); err != nil {
    log.Fatalf("could not activate BEE: %v", err)
}
```

```
module github.com/usbarmory/GoTEE           go.mod
go 1.25.0

require github.com/usbarmory/tamago v1.25.0
```

TamaGo allows creation of true unikernels, incorporating in a single binary boot code, peripheral drivers, libraries and application code with minimal dependencies and all the benefits of the full Go ecosystem, including supply chain security, build reproducibility and debugging.

# Improving memory safety

■ memory-unsafe programming language  
■ memory-safe programming language

TamaGo allows a dramatic reduction of the attack surface by **removing any dependency on memory-unsafe languages** (e.g. C), Operating Systems and third party libraries.

# Developing, building and running

The full Go runtime is supported<sup>1</sup> without any specific changes required on the application side (Rust on bare metal<sup>2</sup>, for comparison, requires `#![no_std]` pragma).

```
package main

import (
    _ "github.com/usbarmory/tamago/board/usbarmory/mk2"
)

func main() {
    // your code
}
```

```
GOOS=tamago GOARM=7 GOARCH=arm
${TAMAGO} build -ldflags "-T 0x80010000 -R 0x1000" main.go
```

All Go ecosystem features in terms of build reproducibility, dependency management, profiling, debugging, remain intact.

Firmware/unikernels can be compiled just as easily on Linux, Windows, macOS.

1. The application requires a single import for the board package to enable necessary initializations.
2. Go code can be written with very few limitations and the SoC package exposes driver APIs.
3. go build can be used as usual (reproducible builds!) with few linker flags to define entry point.
4. SoC and KVM packages support native loading (no bootloader!).

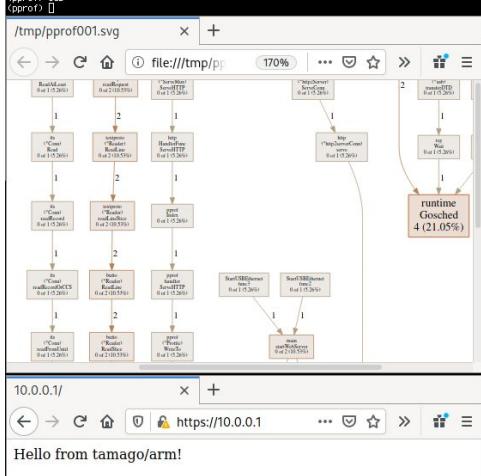

<sup>1</sup> <https://github.com/usbarmory/tamago/wiki/Compatibility>

<sup>2</sup> <https://rust-embedded.github.io/book/intro/no-std.html>

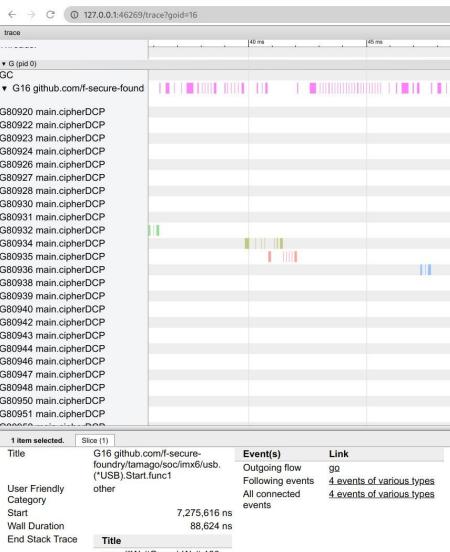

# Debugging

```
[[ go tool pprof http://10.0.0.1:80/debug/pprof/goroutine
Fetching profile over HTTP from http://10.0.0.1:80/debug/pprof/goroutine
Saved profile in /home/luca/Downloads/pprof/goroutine.826.pb.gz
Type: goroutine
Time: Jan 1, 1970 at 1:03am (CET)
Entering interactive mode (type "help" for commands, "o" for options)
(pprof) web
```

GDB can be used as usual, on emulated (QEMU) targets or real ones (JTAG).

The `pprof` package can be used as usual for tracing or profile guided optimization.

```

# TamaGo runtime API

As part of the upstreaming proposal, the implementation of GOOS=tamago has been refined in a “Rosetta Stone” for integration of a freestanding Go runtime.

MMU initialization, exception and IRQ handling are implemented outside the Go runtime and imported as architecture packages (e.g. amd64, arm).

This means low-level APIs (e.g. TrustZone), networking, can can be regular packages.

The Go runtime modifications are board and architecture independent.

This entails that hardware ports can be achieved through external packages, whether bare metal, OS kernel space, OS user space, TEE monitor or TEE applet.

# Go runtime “Rosetta Stone”

## Proposal Details

I propose the addition of a new `GOOS=none` target, such as `GOOS=none`, to allow Go runtime execution under specific application defined exit functions, rather than arbitrary OS syscalls, enabling freestanding execution without direct OS support.

This is currently implemented in the [GOOS=tamago](#) project, but for reasons laid out in the *Proposal Background* section it is proposed for upstream inclusion.

Go applications built with `GOOS=none` would run on bare metal, without any underlying OS. All required support is provided by the Go runtime and external driver packages, also written in Go.

## Go runtime changes

### Note

The changes are also documented in package [tamago/doc](#)

A working example of all proposed changes can be found in the [GOOS=tamago implementation](#).

Board support packages or applications would be required (only under `GOOS=none`) to define the following functions to support the runtime.

If the use of `go:linkname` is undesirable different strategies are possible, right now linkname is used as convenient way to have externally defined functions being directly invoked in the runtime early on.

These hooks act as a “Rosetta Stone” for integration of a freestanding Go runtime within an arbitrary environment, whether bare metal or OS supported.

For bare metal examples see the following packages: [usbarmory](#), [uefi](#), [microvml](#).

For OS supported examples see the following tamago packages: [linux](#), [applet](#).

## Index

### reference

- [Variables](#)

# Go runtime API

```
func GetRandomData(b []byte)
```

Must be linked as `runtime.GetRandomData`, generates `len(b)` random bytes and writes them into `b`.

```
func InitRNG()
```

Must be linked as `runtime.initRNG`, initializes random number generation.

```
// defined in rng.s                                              amd64/rng.go
func rdrand() uint32

// GetRandomData returns len(b) random bytes gathered from the RDRAND instruction.
//
//go:linkname GetRandomData runtime.GetRandomData
func GetRandomData(b []byte) {
    read := 0
    need := len(b)

    for read < need {
        read = rng.Fill(b, read, rdrand())
    }
}

//go:linkname initRNG runtime.initRNG
func initRNG() {}
```

# Go runtime API

```
func Hwinit0()
```

Must be linked as `runtime.hwinit0`, takes care of lower level initialization triggered before runtime setup (pre World start).

```
func Hwinit1()
```

Must be linked as `runtime.hwinit1`, takes care of lower level initialization triggered early in runtime setup (post World start).

```
//go:linkname Init runtime.hwinit0          arm/init.go

func Init() {
    if int(read_cpsr())&0x1f != SYS_MODE {
        // initialization required only when in PL1
        return
    }

    vfp_enable()
}
```

It must be defined using Go's Assembler to retain Go's commitment to backward compatibility.

Otherwise care must be taken as the lack of World start does not allow memory allocation.

```
//go:linkname Init runtime.hwinit1          microvm/microvm.go

func Init() {
    // initialize CPU
    AMD64.Init()

    // initialize I/O APIC
    IOAPIC0.Init()

    // initialize serial console
    UART0.Init()

    runtime.Exit = func(_ int32) {
        AMD64.Reset()
    }
}
```

# Go runtime API

```
func Nanotime() int64
```

Must be linked as `runtime.nanotime1`, returns the system time in nanoseconds.

```
func Printk(c byte)
```

Must be linked as `runtime.printk`, handles character printing to standard output.

```
//go:linkname nanotime1 runtime.nanotime1
func nanotime1() int64 {
    return ARM.GetTime()
}
```

imx6ul/timer.go

```
func (cpu *CPU) GetTime() int64 {
    return int64(float64(read_cntpct())*cpu.TimerMultiplier) + cpu.TimerOffset
}
```

arm/timer.go

```
//go:linkname printk runtime.printk
func printk() {
    imx6ul.UART2.Tx(c)
}
```

usbarmory/mk2/console.go

Must be defined using Go's Assembler to retain Go's commitment to backward compatibility.

Otherwise care must be taken as the lack of World start does not allow memory allocation.

# Go runtime API

RAM layout defined by architecture and board packages

```
var ramStart uint  
var ramSize uint  
var ramStackOffset uint
```

```
//go:linkname ramStart runtime.ramStart  
var ramStart uint32 = MMDC_BASE  
  
//go:linkname ramSize runtime.ramSize  
var ramSize uint32 = 0x20000000 // 512MB
```

imx6ul/timer.go  
usbarmory/mk2/mem.go

CPU idle time management (optional)

```
var Idle func(until int64)
```

```
func (cpu *CPU) Init(vbar uint32) {  
    runtime.Idle = func(pollUntil int64) {  
        // we have nothing to do forever  
        if pollUntil == math.MaxInt64 {  
            cpu.WaitInterrupt()  
        }  
    }  
}
```

arm/arm.go

Runtime termination (optional)

```
var Exit func(code int32)
```

Network socket implementation (optional)

```
var SocketFunc func(ctx context.Context,  
    net string,  
    family, sotype int,  
    laddr, raddr Addr) (interface{}, error)
```

```
func (iface *Interface) Socket(ctx context.Context ...) {  
    ...  
    gonet.DialContextTCP(ctx, stack, rFullAddr, proto)  
}  
  
// hook interface to Go runtime  
net.SocketFunc = iface.Socket
```

imx-enet/runtime.go  
tamago-example/network/imx-enet.go

# Go runtime API

SMP

HW/OS threading (optional)

```
var Task func(sp mp, gp, fn unsafe.Pointer)
```

The call is invoked only when `runtime.GOMAXPROCS > 1`.

The initialization of supplemental cores (APs) is entirely outside the Go distribution, only `Task` is required as runtime hook.

    RET
```

A single unified Go file allows hookup of TamaGo runtime API back to Linux.

Architecture specific Go assembly files, which are verbatim copies of relevant functions from sys\_linux\_{amd64,arm,arm64,riscv64}.s provide Linux system call hooks.

This approach allow creation of support for GOOS=tamago in OS userspace for testing and user/linux packages.

# Userspace execution

---

```
package main

import (
    "fmt"
    "net"
    "os"

    _ "github.com/usbarmory/tamago/user/linux"
)

func main() {
    _, err := net.Dial("tcp", "8.8.8.8:53")
    fmt.Printf("** I can't get out!    ;-( ** %s\n", err)

    _, err = os.ReadFile("/etc/passwd")
    fmt.Printf("** I can't get out!    ;-( ** %s\n", err)
}

$ GOOS=tamago ./bin/go run main.go

** I can't get out!    ;-( ** dial tcp 8.8.8.8:53: net.SocketFunc is nil
** I don't see the FS! ;-( ** open /etc/passwd: No such file or directory
```

Any imported package can implement the required runtime changes with OS supervision instead of bare metal drivers.

This allows user space execution with the benefit of system calls isolation.

The executable cannot leverage on the Go runtime to directly access OS resources.

This allows custom APIs for networking, RNG, time handling and is also used for Trusted Applet implementation (see later GoTEE coverage).

<https://github.com/usbarmory/tamago/wiki#userspace-targets>

# Go distribution testing for GOOS=tamago

---

```
$ cd tamago-go
$ GO_BUILDER_NAME=tamago GOOS=tamago GOARCH=arm64 ./bin/go tool dist test

```

Demonstrates importing, execution and test compliance for the entire Go stdlib on **GOARCH={amd64, arm, arm64, riscv64}**.

Runs under Linux (natively or using qemu via binfmt\_misc) bridging required external functions with Linux syscalls.

In-memory filesystem and networking support testdata access and network tests.

<https://github.com/usbarmory/tamago/wiki/Compatibility>

# Releases

## v1.25.2 Latest

This release introduces improved CPU idle management support functions for `amd64`, extending the [pattern enabled by the previous release on single-core](#) to multi-core CPUs:

```
runtime.Idle = func(pollUntil int64) {
    if pollUntil == 0 {
        return
    }

    cpu.SetAlarm(pollUntil)
    cpu.WaitInterrupt()
    cpu.SetAlarm(0)
}
```

Major changes for [tamago package API](#):

- `amd64`, `arm`, `riscv64`: `(*CPU).DefaultIdleGovernor` new function to export default CPU idle time management
- `amd64.(*CPU).ClearInterrupts`: new function to signal end-of-interrupt safely under SMP ([#e4346ed](#))
- `amd64.(*CPU).EnableInterrupts`: function deprecated in favor of `(*CPU).ClearInterrupts` ([#e4346ed](#))

Major changes for tamago package internals:

- `amd64`: interrupt are now enabled on supplemental cores (APs)
- `amd64`: IRQ handling implementation improved to prevent SMP race conditions
- `amd64`: tight loops on register wait are now avoided also under SMP ([#c4bd784](#))
- `amd64`: fix page tables setup for correct operation under WSL and Google Cloud KVMs ([#53](#))

Full Changelog: [v1.25.1...v1.25.2](#)

This release requires `GOOS=tamago` support in the Go distribution, it requires at least [tamago-go1.25.2](#).

<a href="#"> Source code (tar.gz)</a>	2 minutes ago

<https://github.com/usbarmory/tamago/releases>

## tamago-go1.25.2 Latest

This is a release for the Go distribution as modified by the [TamaGo framework](#), which enables compilation and execution of unencumbered Go applications on bare metal AMD64/ARM/RISC-V processors.

This release adds `GOOS=tamago` support to [Go 1.25.2](#).

Major changes for `GOOS=tamago` `GOARCH=amd64` [runtime API](#):

- `runtime.Asleep`: new function to verify targets for `runtime.Wake` and aid race-free SMP ISR patterns ([#3d633a7](#))
- `testing`: new `user_linux` build tag now [required](#) with `go test` to distinguish from regular `testing` import ([#6d5e3fe](#))

Major changes for `GOOS=tamago` runtime internals:

- added support for `GOOS=arm64` ([#113](#))
- `testing`: relocated testing runtime initialization to fix [test run detection for all platforms](#) ([#631b797](#))

Full Changelog: [tamago-go1.25.1...tamago-go1.25.2](#)

Upstream comparison: [go1.25.2...tamago-go1.25.2](#)

### Release binaries

The release assets include the pre-compiled modified Go distribution required to compile [applications using the TamaGo framework](#) on amd64 and armv7l (such as the [USB armory Mk II](#)) Linux hosts.

Installation:

```
sudo tar -xvf tamago-go<version>.linux-<arch>.tar.gz -C /
```

You should now be able to compile the [example application](#) by setting the `TAMAGO` environment variable as follows:

```
export TAMAGO=/usr/local/tamago-go/bin/go
```

# i.MX6ULZ driver: Data Co-Processor (DCP)

The DCP provides hardware accelerated crypto functions and use of the SoC unique OTPMK key for device unique encryption/decryption operations. The driver takes ~450 LOC.

```
workPacket := WorkPacket{}
workPacket.Control0 |= (1 << DCP_CTRL0 OTP_KEY)
...
workPacket.Control1 |= (AES128 << DCP_CTRL1_CIPHER_SELECT)
workPacket.Control1 |= (CBC << DCP_CTRL1_CIPHER_MODE)
workPacket.Control1 |= (UNIQUE_KEY << DCP_CTRL1_KEY_SELECT)

workPacket.BufferSize = uint32(len(diversifier))
workPacket.SourceBufferAddress = dma.Alloc(diversifier, 0)
defer dma.Free(workPacket.SourceBufferAddress)

workPacket.DestinationBufferAddress = dma.Alloc(key, 0)
defer dma.Free(workPacket.DestinationBufferAddress)

workPacket.PayloadPointer = dma.Alloc(iv, 0)
defer dma.Free(workPacket.PayloadPointer)

buf := new(bytes.Buffer)
binary.Write(buf, binary.LittleEndian, &workPacket)

pkt := dma.Alloc(buf.Bytes(), 0)
defer dma.Free(pkt)

reg.Write(HW_DCP_CH0CMDPTR, pkt)
reg.Set(HW_DCP_CHOSEMA, 0)
```

```
diversifier := []byte{0xde, 0xad, 0xbe, 0xef}
iv := make([]byte, aes.BlockSize)

key, err := imx6.DCP.DeriveKey(diversifier, iv)
```

```
-- i.mx6 dcp -----
imx6_dcp: derived test key 75f9022d5a867ad430440feec6611f0a
```

USB armory Mk II example DCP + SNVS run (w/ Secure Boot)

```
-- i.mx6 dcp -----
imx6_dcp: error, SNVS unavailable, not in trusted or secure state
```

USB armory Mk II example DCP + SNVS run (w/o Secure Boot)

Note that Go defined structs (such as `WorkPacket`) can be easily made C-compatible<sup>1</sup> if required.

On i.MX6UL a full CAAM driver is available.

## type CAAM

CAAM represents the Cryptographic Acceleration and Assurance Module instance.

### func (\*CAAM) DeriveKey

```
func (hw *CAAM) DeriveKey(diversifier []byte, key []byte) (err error)
```

DeriveKey derives a hardware unique key in a manner equivalent to NXP Symmetric key diversifications guidelines (AN10922 - Rev. 2.2) for AES-256 keys.

The diversifier is used as message for AES-256-CMAC authentication using a blob key encryption key (BKEK) derived from the hardware unique key (internal OTPMK, when SNVS is enabled, through Master Key Verification Blob).

\*WARNING\*: when SNVS is not enabled a default non-unique test vector is used and therefore key derivation is *\*unsafe\**, see snvs.Available().

The unencrypted BKEK is used through DeriveKeyMemory. An output key buffer previously created with DeriveKeyMemory.Reserve() can be used to avoid external RAM exposure, when placed in iRAM, as its pointer is directly passed to the CAAM without access by the Go runtime.

# i.MX6ULZ driver: Random Number Generator

The RNGB provides a hardware True Random Number Generator, useful to gather the initial seed on embedded systems without a battery backed RTC (and not much else<sup>1</sup>). The driver takes ~80 LOC and is hooked as provider for crypto/rand.

```
var getRandomDataFn func([]byte)

//go:linkname getRandomData runtime.getRandomData
func getRandomData(b []byte) {
    getRandomDataFn(b)
}

func (hw *rngb) getRandomData(b []byte) {
    read := 0
    need := len(b)

    for read < need {
        if reg.Get(hw.status, HW_RNG_SR_ERR, 0x1) != 0 {
            panic("imx6_rng: panic\n")
        }

        if reg.Get(hw.status, HW_RNG_SR_FIFO_LVL, 0xf) > 0 {
            val := *hw fifo
            read = fill(b, read, val)
        }
    }
}
```

```
for i := 0; i < 10; i++ {
    rng := make([]byte, size)
    rand.Read(rng)
    fmt.Printf("%x\n", rng)
}
```

```

USB armory Mk II example TRNG run

<sup>1</sup> [https://media.ccc.de/v/32c3-7441-the\\_plain\\_simple\\_reality\\_of\\_entropy](https://media.ccc.de/v/32c3-7441-the_plain_simple_reality_of_entropy)

# i.MX6ULZ driver: USB

```
func buildDTD(n int, dir int, ioc bool, addr uint32, size int) (dtd *dTD) {
    dtd = &dTD{};

    // interrupt on completion (ioc)
    if ioc {
        bits.Set(&dtd.Token, 15)
    } else {
        bits.Clear(&dtd.Token, 15)
    }

    // invalidate next pointer
    dtd.Next = 0b1

    // multiplier override (Mult0)
    bits.SetN(&dtd.Token, 10, 0b11, 0)
    // active status
    bits.Set(&dtd.Token, 7)

    // total bytes
    bits.SetN(&dtd.Token, 16, 0xffff, uint32(size))

    dtd._buf = addr
    dtd._size = uint32(size)

    for n := 0; n < DTD_PAGES; n++ {
        dtd.Buffer[n] = dtd._buf + uint32(DTD_PAGE_SIZE*n)
    }

    buf := new(bytes.Buffer)
    binary.Write(buf, binary.LittleEndian, dtd)
    dtd._dtd = dma.Alloc(buf.Bytes()[0:DTD_SIZE], DTD_ALIGN)

    return
}
```

Example of Endpoint Transfer Descriptor (dTD) configuration.

A custom DMA allocator is used to copy structures on memory reserved for DMA operation, with required alignments.

```
addr = dma.Alloc(buf, align)
defer dma.Free(addr)
```

Buffers can be also reserved by the application to spare re-allocation (automatic detection of slices already in DMA memory).

Using Go goroutines, channels, mutexes, interfaces freely in low level drivers is a delight!

All in ~1200 LOC !

# i.MX6ULZ driver: USB networking

```
func configureEthernetDevice(device *usb.Device) {
    // Supported Language Code Zero: English
    device.SetLanguageCodes([]uint16{0x0409})

    // device descriptor
    device.Descriptor = &usb.DeviceDescriptor{}
    device.Descriptor.SetDefaults()
    device.Descriptor.DeviceClass = 0x2
    device.Descriptor.VendorId = 0x0525
    device.Descriptor.ProductId = 0xa4a2
    device.Descriptor.Device = 0x0001
    device.Descriptor.NumConfigurations = 1

    iManufacturer, _ := device.AddString(`TamaGo`)
    device.Descriptor.Manufacturer = iManufacturer

    iProduct, _ := device.AddString(`RNDIS/Ethernet Gadget`)
    device.Descriptor.Product = iProduct

    iSerial, _ := device.AddString(`0.1`)
    device.Descriptor.SerialNumber = iSerial

    // device qualifier
    device.Qualifier = &usb.DeviceQualifierDescriptor{}
    device.Qualifier.SetDefaults()
    device.Qualifier.DeviceClass = 2
    device.Qualifier.NumConfigurations = 2
}
```

```
func configureECM(device *usb.Device) {
...
    conf.Interfaces = append(conf.Interfaces, iface)

```

The USB Ethernet (CDC ECM) Driver is integrated with Google netstack (gvisor.dev/gvisor/pkg/tcpip) for pure Go networking.

```
func ECMTx(_ []byte, lastErr error) ([]byte) {
    // gvisor tcpip channel link
    pkt := <-link.C:

...
    // Ethernet frame header
    in = append(in, hostMAC...)
    in = append(in, deviceMAC...)
    in = append(in, proto...)
    // packet header
    in = append(in, hdr...)
    // payload
    in = append(in, payload...)

    return
}

func ECMRx(out []byte, lastErr error) ([]byte) {
...
    pkt := tcpip.PacketBuffer{
        LinkHeader: hdr,
        Data:       payload,
    }

    // gvisor tcpip channel link
    link.InjectInbound(proto, pkt)

    return
}
```

# i.MX6ULL driver: Ethernet networking

```
func (ring *bufferDescriptorRing) init(rx bool, n int) uint32 {
    ring.size = n
    ring.bds = make([]*bufferDescriptor, n)

    descSize := len(&bufferDescriptor{}).Bytes()

# GoKey - The bare metal Go smart card

The GoKey application implements a composite USB device implementing an [OpenPGP 3.4](#) smartcard, a [FIDO U2F](#) token, an [age plugin](#) and a [PKCS#11 over RPC](#) server, written in pure Go (~2700<sup>1</sup> LOC).

It allows to implement a radically different security model for smartcards, taking advantage of Go to safely mix layers and protocols not easy to combine.

For instance authentication can happen over SSH instead of plaintext PIN transmission over USB.

	Trust anchor	Data protection	Runtime	Application	Requires tamper proofing	Encryption at rest
<b>traditional smartcard</b>	flash protection	flash protection	JCOP	JCOP applets	Yes	No
<b>USB armory with GoKey</b>	secure boot	SoC security element	TamaGo	Go application	No	Yes

# Demo: GoKey

<https://github.com/usbarmory/gokey>

<https://youtu.be/WeO2eiYSeWM>

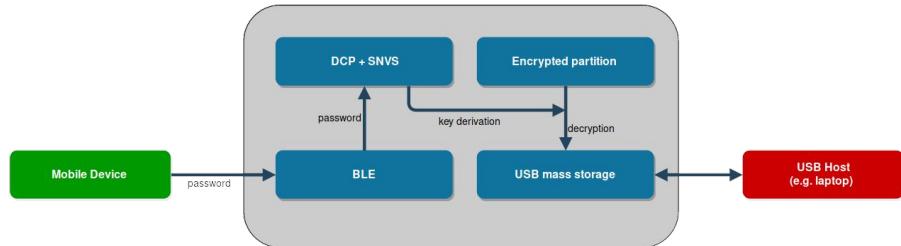

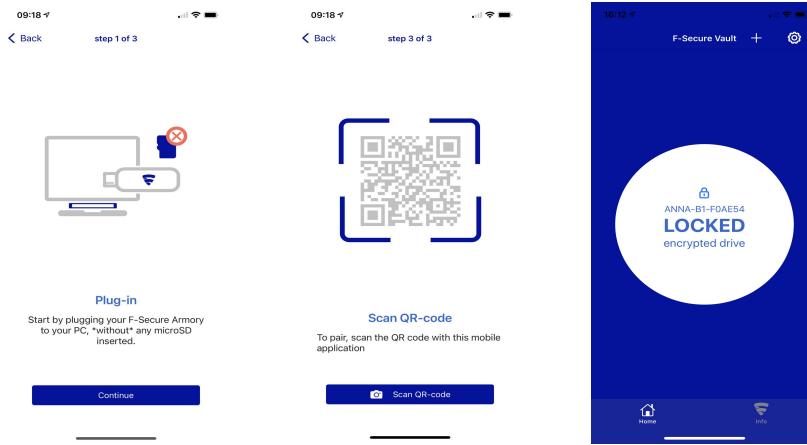

# Armory Drive - Encrypted USB Mass Storage

Armory Drive implements the **easiest to use encrypted drive solution** allowing secure access to any microSD card.

Unlike existing encrypted drive solutions the key is unlocked with **3 factors** (user + mobile phone + armory) and **over Bluetooth**. No trust (or driver requirements) are delegated to the host.

It consists of **~3000 LOC** of pure TamaGo code and an iOS app.

It uses Google Firmware Transparency framework to enable firmware update authentication on the installer as well as the device itself.

# armory-boot - USB armory boot loader

A primary signed boot loader (~700 LOC) to launch authenticated Linux kernel images on secure booted<sup>1</sup> USB armory boards, replacing U-Boot.

```
func boot(kernel uint, params uint, cleanup func(), region *dma.Region) (err error) {
    table := arm.SystemVectorTable()
    table.Supervisor = exec

    imx6ul.ARM.SetVectorTable(table)

    _kernel = uint32(kernel)
    _params = uint32(params)
    _mmu = (region != nil)

    cleanup()

    if region != nil {
        imx6ul.ARM.SetAttribute(
            uint32(region.Start()),
            uint32(region.End()),
            arm.TTE_EXECUTE_NEVER, 0)
    } else {
        imx6ul.ARM.FlushDataCache()
        imx6ul.ARM.DisableCache()
    }

    svc()

    return errors.New("supervisor failure")
}
```

```
func verifySignature(buf []byte, s []byte) (valid bool, err error) {
    sig, err := DecodeSignature(string(s))

    if err != nil {
        return false, fmt.Errorf("invalid signature, %v", err)
    }

    pub, err := NewPublicKey(PublicKeyStr)

    if err != nil {
        return false, fmt.Errorf("invalid public key, %v", err)
    }

    return pub.Verify(buf, sig)
}

func verifyHash(buf []byte, s string) bool {
    // use hardware acceleration
    sum, _ := imx6ul.DCP.Sum256(buf) {

        if hash, err := hex.DecodeString(s); err != nil {
            return false
        }

        return bytes.Equal(sum[:], hash)
    }
}
```

## **type ELFImage**

```
type ELFImage struct {  
    // Region is the memory area for image loading.  
    Region *dma.Region  
    // ELF is a bootable bare-metal ELF image.  
    ELF []byte  
    // contains filtered or unexported fields  
}
```

## **func (\*ELFImage) Boot**

```
func (image *ELFImage) Boot(cleanup func()) (err error)
```

Boot calls a loaded bare-metal ELF image.

## **func (\*ELFImage) Entry**

```
func (image *ELFImage) Entry() uint
```

Entry returns the image entry address.

## **func (\*ELFImage) Load**

```
func (image *ELFImage) Load() (err error)
```

Load loads a bare-metal ELF image in memory.

ELFImage represents a bootable bare-metal ELF image.

```
import (  
    "github.com/usbarmy/armory-boot/exec"  
)  
  
image := &exec.ELFImage{  
    Region: mem,  
    ELF:     os.Firmware,  
}  
  
if err = image.Load(); err != nil {  
    panic(fmt.Sprintf("load error, %v\n", err))  
}  
  
log.Printf("armored-witness-boot: starting kernel@%.8x\n", image.Entry())  
  
if err = image.Boot(preLaunch); err != nil {  
    panic(fmt.Sprintf("armored-witness-boot: load error, %v\n", err))  
}
```

# go-boot - UEFI boot manager

A TamaGo unikernel implementing a **UEFI Shell** and **OS loader** for AMD64 platforms.

It supports loading of arbitrary EFI images, Linux kernels and Windows UEFI boot manager.

It provides a clean pure Go API to UEFI Boot and Runtime services in ~2000 LOC.

It results in a 3MB EFI application which performs as fast, if not faster, than equivalent functionality  
Implemented in other C/Rust based efforts.

It supports **UEFI networking** through SNP, bringing full Go network I/O in your pre-boot environment.

```
initializing EFI services
initializing console (text)

go-boot * tamago/amd64 (go1.24.2) * UEFI x64

> gemini I am talking to you from an UEFI bootloader, isn't that amazing? Shall I  
boot Linux or Windows today?
```

That \*is\* amazing! It's cool to think I'm communicating with you directly from the UEFI environment.

As for your question, whether to boot Linux or Windows is entirely up to you! It depends on what you want to do today. Here's a little thought process to help you decide:

- \* \*\*\*What tasks do you have planned?\*\*  
 \* \*\*Linux:\*\* If you're planning on doing software development, system administration, using specific Linux-only tools, or prefer its command-line environment, Linux might be the better choice.  
 \* \*\*Windows:\*\* If you're planning on gaming, using Windows-specific applications (like Microsoft Office), or prefer its user interface, Windows might be the better choice.
- \* \*\*\*What are you in the mood for?\*\*  
 \* Sometimes, it's just about which operating system you feel like using!

Ultimately, the decision is yours. Have fun with whichever OS you choose! Let me know if you need any more help or have any other questions.

# type Services

Services represents the UEFI services instance.

```
type Services struct {
    // EFI System Table instance
    SystemTable *SystemTable

    // UEFI services
    Console *Console
    Boot    *BootServices
    Runtime *RuntimeServices
    // contains filtered or unexported fields
}
```

## func (\*Services) Address

```
func (s *Services) Address() uint64
```

Address returns the EFI System Table pointer.

```
import (
    "github.com/usbarmory/go-boot/uefi"
)

UEFI := &uefi.Services{}

if err = UEFI.Init(imageHandle, systemTable); err != nil {
    panic(fmt.Sprintf("could not initialize EFI services, %v\n", err))
}

root, _ = UEFI.Root()
UEFI.Boot.LoadImage(0, root, "EFIShell.efi")
```

## func (\*Services) Root

```
func (s *Services) Root() (root *FS, err error)
```

Root returns an EFI Simple File System instance for the current EFI image root volume.

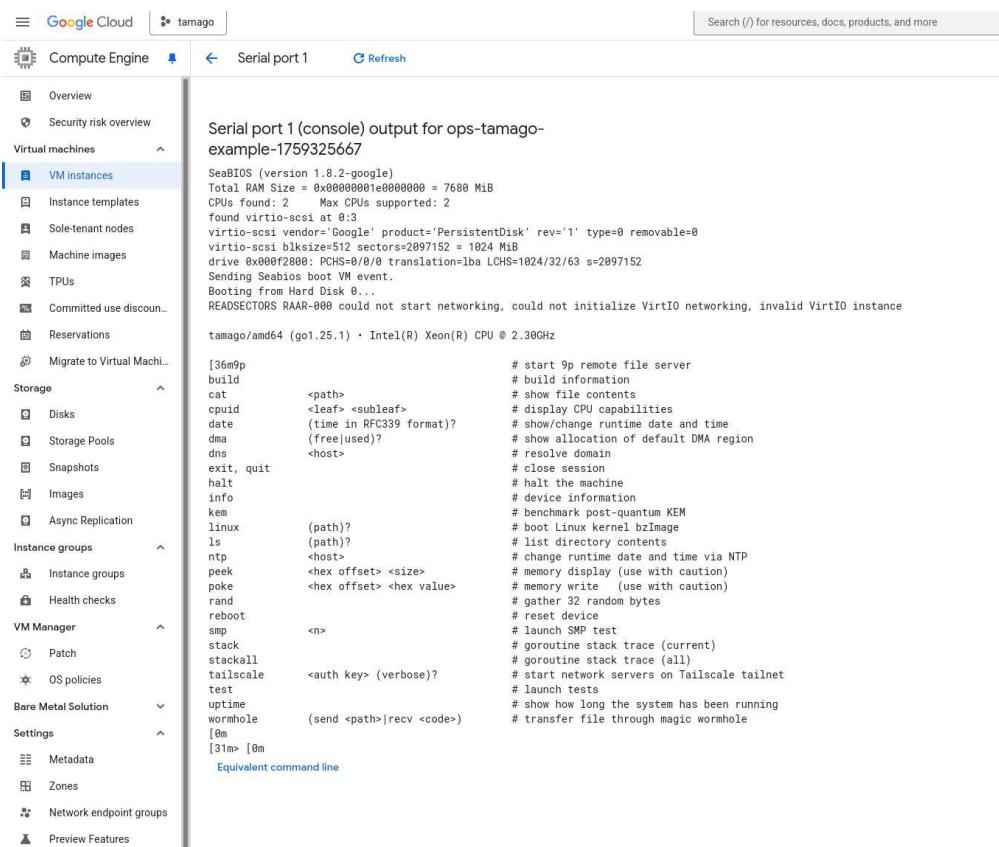

# Support for cloud deployments

TamaGo Unikernels can be converted to raw MBu disk images to be launched as VMs on **Google Compute Engine** or **Amazon EC2**.

On compute platforms with UEFI support it is also possible to simply boot as UEFI binary.

This is supported by tamago BSP  
google/gcp and go-boot BSP uefi/x64.

```
> info
Runtime .....: go1.25.5 tamago/amd64 GOMAXPROCS=1
RAM .....: 0x10000000-0x50000000 (1024 MiB)
Board .....: gcp
CPU .....: AMD EPYC 7B13
Cores .....: 1
Frequency ....: 2.451697 GHz
VirtIO Net0 ...: 42:01:0a:84:00:02
```

The screenshot shows the Google Cloud Compute Engine interface. On the left, a sidebar lists categories like Overview, Security risk overview, Virtual machines, VM instances, Instance templates, Sole-tenant nodes, Machine images, TPUs, Committed use discount, Reservations, Migrate to Virtual Machine, Storage, Disks, Storage Pools, Snapshots, Images, Async Replication, Instance groups, Health checks, VM Manager, Patch, OS policies, Bare Metal Solution, Settings, Metadata, Zones, Network endpoint groups, and Preview Features. The main pane displays the output of a serial port (Serial port 1) for a VM named 'ops-tamago-example-1759325667'. The output includes boot logs for SeaBIOS, CPU information, and various system commands like cat, cpuid, date, dma, dns, exit, halt, info, kem, linux, ls, ntp, peek, poke, rand, reboot, smp, stack, stackcall, tailscale, test, uptime, wormhole, and more, each with a detailed description in comments. At the bottom, it says 'Equivalent command line'.

<https://github.com/usbarmory/tamago-example/tree/master/tools#google-compute-engine>

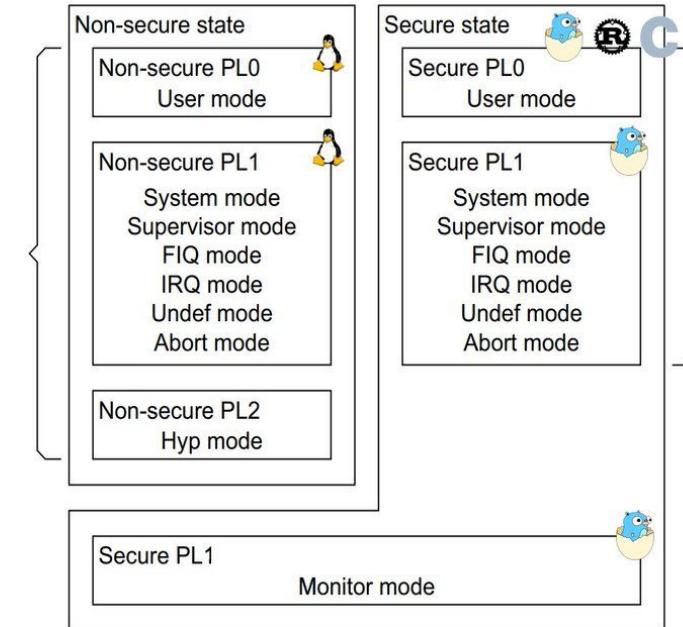

# GoTEE - Trusted Execution Environment

The GoTEE framework implements concurrent instantiation of TamaGo based unikernels in privileged and unprivileged modes, interacting with each other through monitor mode and custom system calls.

With these capabilities GoTEE implements a pure Go Trusted Execution Environment (TEE) bringing Go memory safety, convenience and capabilities to bare metal execution within TrustZone Secure World.

It supports any freestanding user mode applets (e.g. TamaGo, C, Rust) and any “rich” OS running in NonSecure World (e.g. Linux).

## Package monitor

```
type ExecCtx struct {
    R0  uint32
    ...
    R15 uint32 // PC

    // Memory is the executable allocated RAM
    Memory *dma.Region
    // Handler, if not nil, handles user syscalls
    Handler func(ctx *ExecCtx) error
    // Server, if not nil, serves RPC calls over syscalls
    Server *rpc.Server
}
```

### func Load

```
func Load(entry uint, mem *dma.Region, secure bool) (ctx *ExecCtx, err error)
```

Load returns an execution context initialized for the argument entry point and memory region, the secure flag controls whether the context belongs to a secure partition (e.g. TrustZone Secure World) or a non-secure one (e.g. TrustZone Normal World).

### func (\*ExecCtx) Run

```
func (ctx *ExecCtx) Run() (err error)
```

Run starts the execution context and handles system or monitor calls. The execution yields back to the invoking Go runtime only when exceptions are caught. The function invokes the context Handler() and returns when an unhandled exception, or any other error, is raised.

```
import (
    "github.com/usbarmory/armory-boot/exec"
    "github.com/usbarmory/GoTEE/monitor"
)

image := &exec.ELFImage{
    Region: appletRegion,
    ELF:     elf,
}

if err = image.Load(); err != nil {
    return
}

if ta, err = monitor.Load(image.Entry(), image.Region, true); err != nil {
    return nil, fmt.Errorf("SM could not load applet: %v", err)
}

ta.Handler = handler
ta.Server.Register(ctl.RPC)
ta.Run()
```

```

GoTEE supports [lockstep execution](#) of any deterministic execution context, such a Trusted Applet.

The tandem progression of a Trusted Applet executable allows detection of injected or naturally occurred faults.

To achieve this a shadow execution context is paired to the primary one for comparison at each monitor call.

All it takes is the definition of a function that re-configures virtual memory addressing so that the same applet can be allocated in two separate physical memory areas.

```
ta, _ := monitor.Load(taEntry, taMemory, true)
ta.Shadow = ta.Clone()

flags := arm.MemoryRegion|arm.TTE_AP_011<<10

ta.MMU = func() {
    imx6ul.ConfigureMMU(start, end, primaryStart, flags)
}

ta.Shadow.MMU = func() {
    imx6ul.ConfigureMMU(start, end, shadowStart, flags)
}
```

# GoTEE in the wild: space!

On May 22nd 2023 (UTC 05:00:32) the USB armory Mk II got a lift to space!

On February 27th 2024 (UTC 07:27:00) the same unit went back to space.

GoTEE supervised a TamaGo based unikernel (acting as Trusted Applet) and a full Linux instance isolated in NonSecure World to test Post Quantum Key exchanges.

For this occasion TamaGo and GoTEE have been updated with full watchdog and interrupt support.

The payload remained operation for the entire flight duration performing exactly 400 PQC key exchanges. As far as we know this is the first time bare metal Go executed in space.

Andrea Barisani  
@AndreaBarisani

...

Yesterday (UTC 05:00:32) @WithSecure USB armory got a lift (~225 km apogee) from the MAPHEUS-13 rocket launched from the Esrange Space Center.

Thanks to @DLR\_de @adesso\_SE for this amazing collaboration!

Our bare metal GoTEE performed Post Quantum key exchange in space!

# GoTEE in the wild: Armored Witness

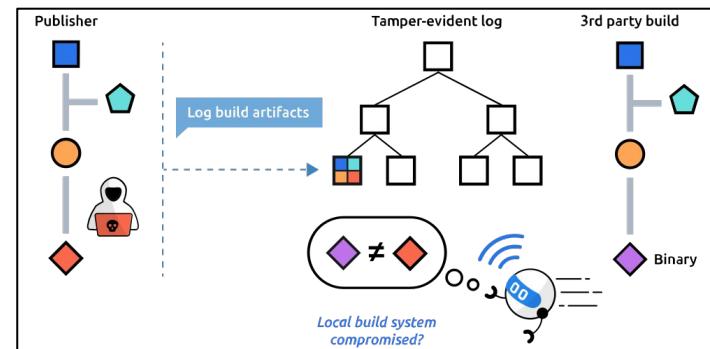

The applet observes public transparency logs verifying that they're operating in an append-only fashion, and counter-signing those checkpoints which it has determined are consistent with all previous checkpoints its seen from the same log.

The counter-signed checkpoints are sent to a **distributor**, which then collates counter-signatures for a given checkpoint from one or more Armored Witness devices, and serves them via a public API.

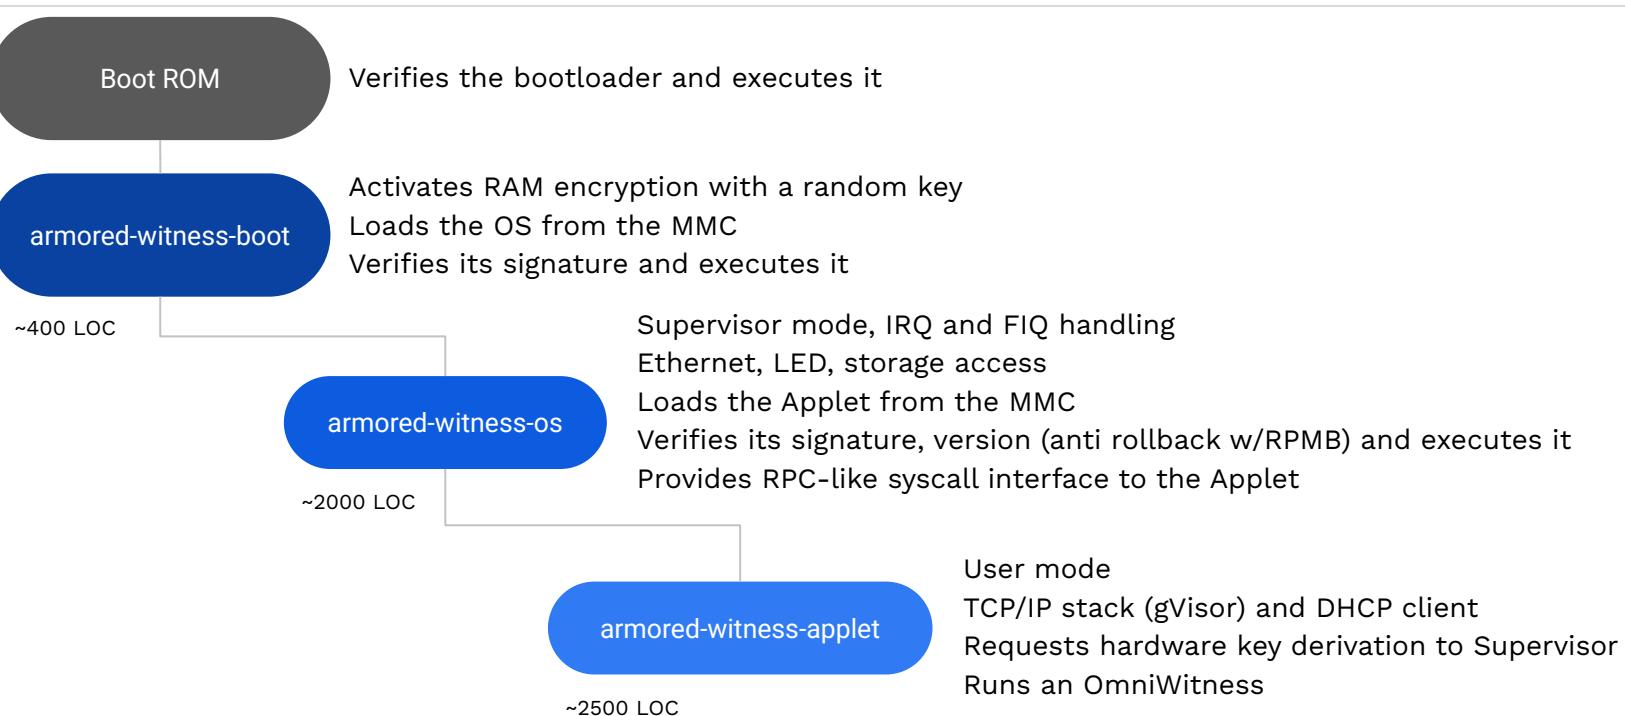

The benefit of this system comes through **removing trust from log operators** to behave honestly, and **placing some of that trust in the witnesses**.

Splitting the trust across multiple parties in this way means that **a larger number of parties must collude to hide malfeasance**, and as other witness implementations/networks start to appear, the number of parties required to collude increases correspondingly.

However, **we can minimise the amount of trust required** to be placed in the Armored Witness by having it be **as transparent as possible** too.

# Armored Witness architecture

All firmware verification past the Boot ROM stage verify, through FT proof bundles, the presence of one or more trusted signatures (multi party signing) on the release manifest. The release manifest includes the binary hash, log checkpoint, the index of the manifest in the log and its corresponding inclusion proof.

**The OS and Applet must be published on the log to be usable on the device.**

<https://github.com/transparency-dev/armored-witness>

# Minimising trust

All firmware is open source, written in TamaGo, and is build-reproducible by anyone. All firmware is logged to a Firmware Transparency log at build and release time.

The provision tool will only use firmware artefacts discovered in the FT log in order to program devices. The on-device self-update process requires that updated firmware is hosted in the FT log.

The verify tool can be used by *custodians* to inspect the device, extract the firmware components from it, and verify that they are present in the FT log.

The verify\_build command continuously monitors the contents of the FT log, and tests that every logged firmware is indeed reproducibly built.

Google is able to quickly become aware of misuse of their signing identities to release unauthorised firmware updates.

**Anyone can verify that each firmware can be rebuilt consistently with what is running, logged and its source.**

# Performance

---

Go code runs (expectedly) with identical, or improved, speed compared to the same code executed under a full blown OS.

TamaGo drivers operates comparably to their Linux counterparts, no serious overhead is present and anyway absolute performance is not a main focus of the effort, which remains security oriented.

Go ECDSA testsuite <sup>1</sup>	TamaGo	Linux
ECDSA sign+verify p224	115 ms	116 ms
ECDSA sign+verify p256	48 ms	46 ms
ECDSA sign+verify p384	1.85 s	1.89 s
ECDSA sign+verify p521	3.48 s	3.60 s

AES-128-CBC encryption w/ DCP	TamaGo	OpenSSL (afalg)
65536 blocks for 10s	6208	4528
4096 blocks for 10s	70326	60204

Go standard libraries run with comparable performance, while TamaGo hardware drivers highlight increased performance.

---

<sup>1</sup> [https://github.com/golang/go/blob/go1.32.0/src/crypto/ecdsa/ecdsa\\_test.go#L76](https://github.com/golang/go/blob/go1.32.0/src/crypto/ecdsa/ecdsa_test.go#L76)

# What have we<sup>1</sup> learned?

---

Bare metal applications can play a big role in the future of secure embedded systems and can be built by **reducing complexity**.

We feel the need for a paradigm shift and think there is no place for C code in complex drivers or applications anymore.

Go is a language that, among others, can definitely play a role in this.

To achieve trust we proved that Go distribution modifications can be minimal to achieve bare metal execution.

We completely **killed C<sup>2</sup>**.

It's all about enabling choice and building trust.

---

<sup>1</sup> "We" as in the authors, but maybe the audience as well.

<sup>2</sup> The SoC boot ROM or BIOS jumps directly to Go runtime.
