Andrea Barisani

Information Security Engineer and Researcher

Founder: **INVERSE PATH** (acquired in 2017)

Head of Hardware Security:  

USB armory  and TamaGo 

Spoke at too many conferences...

Background focused on security auditing and security engineering
on safety critical systems in the automotive, avionics, industrial domains.

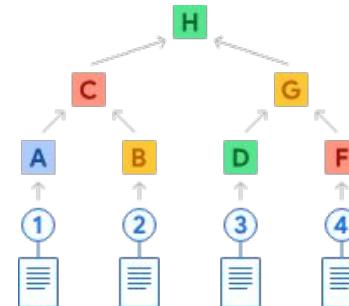

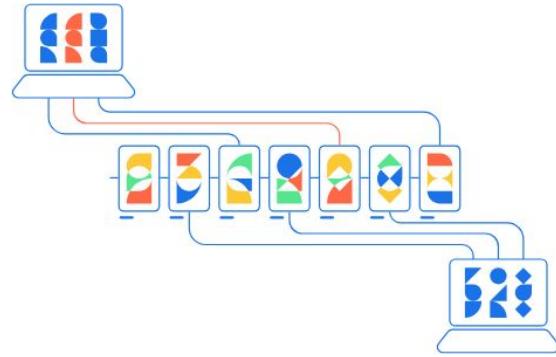

Google Transparency Project

An open-source append only ledger designed to discourage insider threats.

Based on Trillian, an open-source verifiable log.

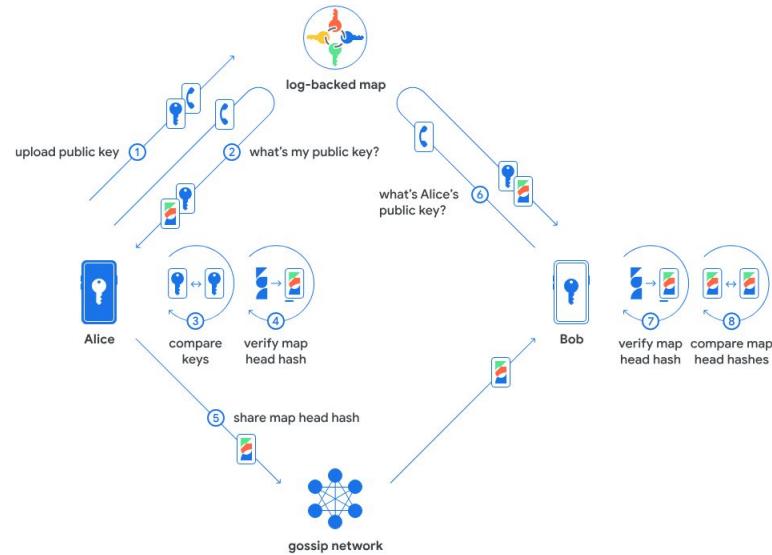

Merkle trees are used, a log record cannot be modified without cascading the change to the tree head hash.

Certificate Transparency

Certificate Transparency allows to see which CAs have issued which certificates, when, and for which domains.

Detect maliciously or mistakenly issued certificates.

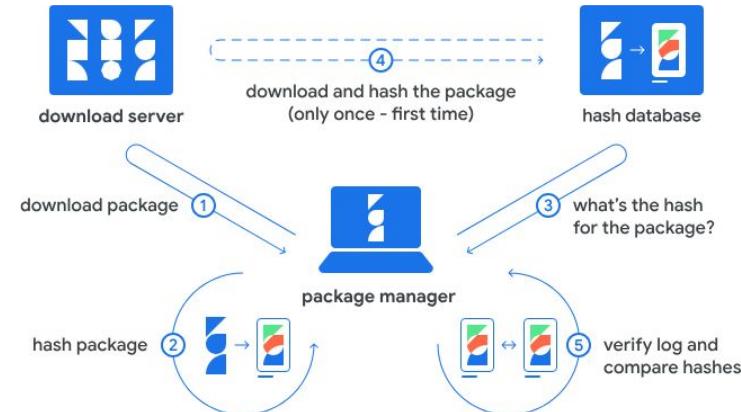

Tamper checking: package managers

A transparent log is hosted on a server and made accessible to clients which are able to verify that a particular log record really is in the log and also that the server never removes any log record from the log.

The log server is not trusted to store the log properly, nor is it trusted to put the right records into the log.

Instead, clients and **auditors interact skeptically with the server**, able to verify for themselves in each interaction that the server really is behaving correctly.

The go command performs “inclusion” proofs (that a specific record exists in the log) and “consistency” proofs (that the tree hasn’t been tampered with) before adding new go.sum lines to the main module’s go.sum file.

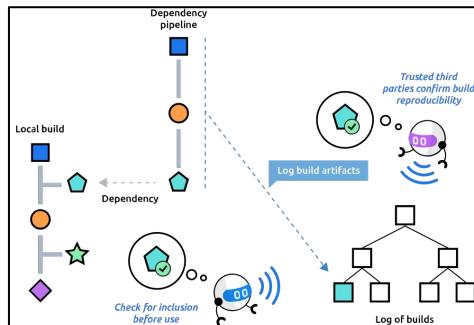

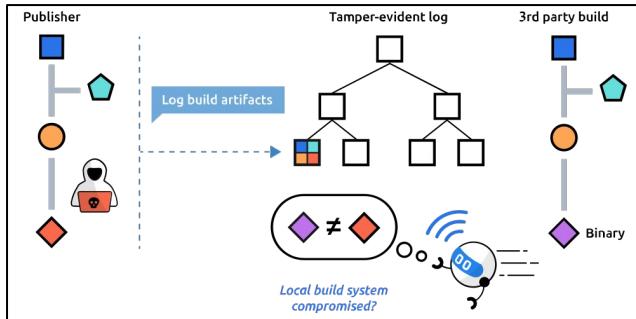

```
module github.com/usbarcery/GoTEE           go.mod
go 1.22.0

require github.com/usbarcery/tamago v0.0.0-20240104082716-7fdd041b36ef
```

```
github.com/usbarcery/tamago v0.0.0-20240104082716-7fdd041b36ef h1:/4FEy+WnOsA06twAR0UWFLEBU2KRhYzkh+jmvlslI4f4=
github.com/usbarcery/tamago v0.0.0-20240104082716-7fdd041b36ef/go.mod h1:uCPXcPo8SZulhZPz8irfVqzwV1PZ45w7CTJxkfxueGA=
```

Binary Transparency

A software supply chain can be protected by an immutable and tamper-evident record which can be viewed and verified by others.

<https://binary.transparency.dev>

Build reproducibility, in combination with tamper evident records, allows verification of opaque firmware binaries required for third party locked down hardware (e.g. secure booted systems).

Release manifest

A JSON *release manifest* exists for every published Armory Drive firmware. This manifest contains information about the release, including the firmware's SHA256 checksum:

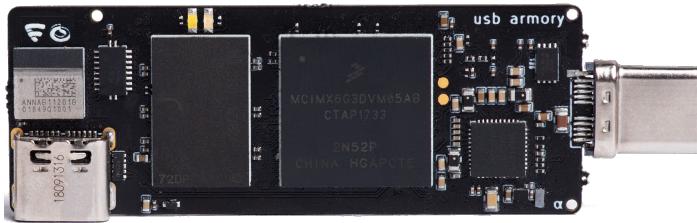

```
{  
    "description": "armory-drive v2021.09.22",  
    "platform_id": "UA-MKII-ULZ",  
    "revision": "v2021.09.22",  
    "artifact_sha256": {  
        "armory-drive.csf": "/f63619GHbwub5gKdaWKP7/DA6/vPoaiJXDFGxfb6vk=",  
        "armory-drive.imx": "MVoRrFrzXT89Gu+F4/aeX12q1gPcRoH1LUR6Kq+6g=",  
        "armory-drive.sdp": "+g9bzK+phhIxbs5786W79poRvLg4T7EnoggDV0E0tL8="  
    },  
    "source_url": "https://github.com/usbarmory/armory-drive/tarball/v2021.09.22",  
    "source_sha256": "6rk8nT+It3k8cJXJ7YK4RvIXEZ16VnkT5xy6iNVbc=",  
    "tool_chain": "tamago version go1.17.1 linux/amd64",  
    "build_args": {  
        "REV": "efeb733"  
    }  
}
```

The manifest is signed with the F-Secure Armory Drive Firmware private key. The signature, in Go sumdb signed note format, is appended to the release manifest:

```
- armory-drive WpWkg+RY85Ha0j+iWxLeWI+GV8eRBnx0ttH7wb3Pu4g5v2E2zChnop0+Ukr77l3YH108+tVwdLiTvVDTasagTsUE
```

These signed release manifests are generated with the `create_release` tool.

<https://github.com/usbarmory/armory-drive/wiki/Firmware-Transparency>

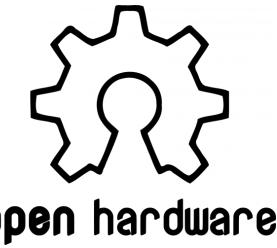

The USB armory is a tiny, but powerful, embedded platform for personal security applications.

Designed to fit in a pocket, laptops, PCs, server and networks.

The USB armory targets the following primary applications:

- Encrypted storage solutions
- Hardware Security Module (HSM)
- Enhanced smart cards
- Electronic vaults (e.g. cryptocurrency wallets) and key escrow services
- Authentication, provisioning, licensing tokens
- USB firewall

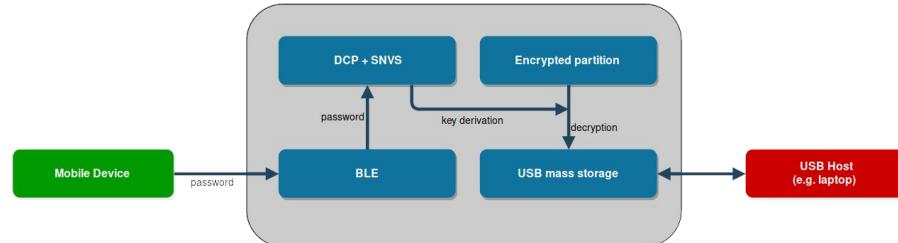

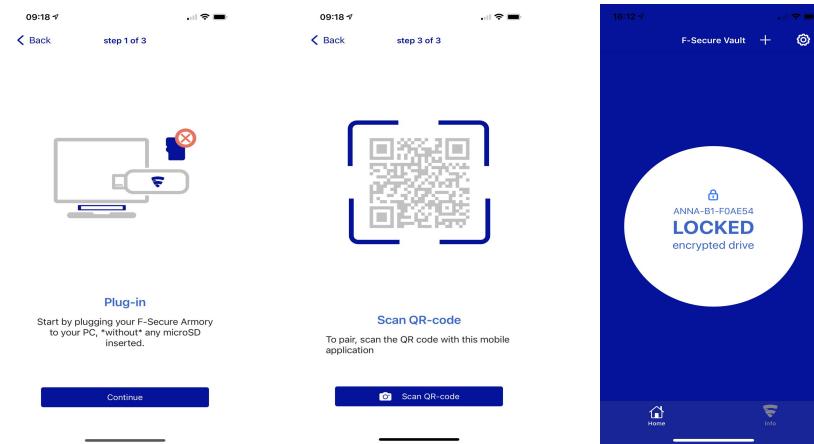

Armory Drive - Encrypted USB Mass Storage

Armory Drive implements the **easiest to use encrypted drive solution** allowing secure access to any microSD card.

Unlike existing encrypted drive solutions the key is unlocked with **3 factors** (user + mobile phone + armory) and **over Bluetooth**. No trust (or driver requirements) are delegated to the host.

It consists of **~3000 LOC** of pure TamaGo (more on this later) code and an iOS app.

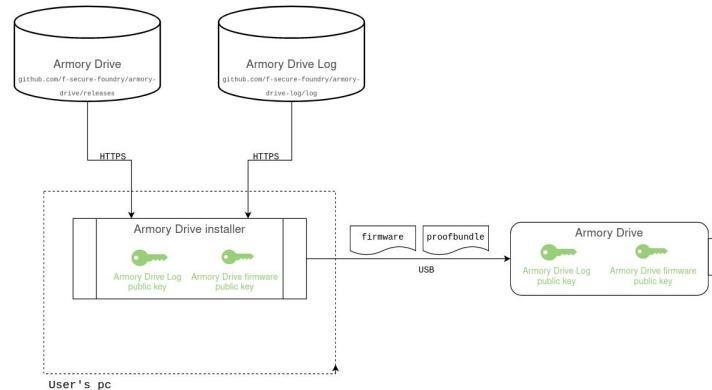

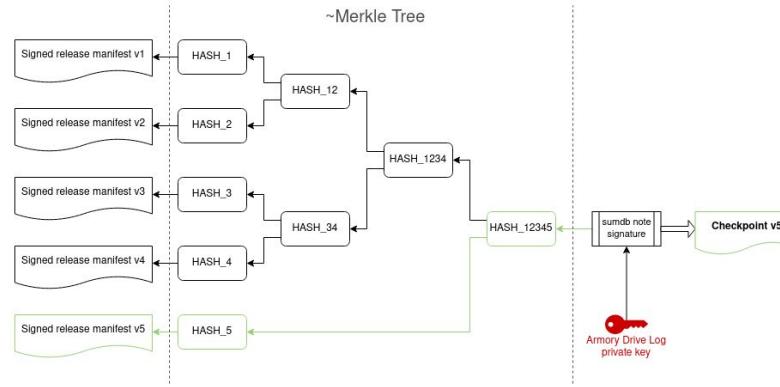

Armory Drive - Encrypted USB Mass Storage

Armory Drive leverages on **Firmware Transparency** to enable advanced firmware update authentication on the installer as well as the device itself.

The installer and firmware work together through a combination of Secure Boot and Firmware Transparency frameworks to authenticate firmware updates.

Secure boot allows firmware authentication with burned in read-only public keys, as well as confidential configuration storage with device specific hardware keys.

Users can choose Secure Boot with own keys, manufacturer keys or none at all (with reduced security).

```
$ armory-drive-install -I
```

Welcome to the Armory Drive installer!

For more information or support on Armory Drive see:
<https://github.com/usbarmory/armory-drive/wiki>

This program will install or upgrade Armory Drive on your USB armory.

This installer supports installation of unsigned or signed Armory Drive releases on the USB armory.

*** Option #1: signed releases ***

The installation of signed releases activates Secure Boot on the target USB armory, fully converting the device to exclusive operation with signed executables.

If the signed releases option is chosen you will be given the option of using F-Secure signing keys or your own.

*** Option #2: unsigned releases ***

The installation of unsigned releases does not leverage on Secure Boot and does not permanently modify the USB armory security state.

Unsigned releases however cannot guarantee device security as hardware bound key material will use default test keys, lacking protection for stored armory communication keys and leaving data encryption key freshness only to the mobile application.

Unsigned releases are recommended only for test/evaluation purposes and are not recommended for protection of sensitive data where device tampering is a risk.

Would you like to use unsigned releases, *without enabling* Secure Boot on the USB armory? (y/N): N

Would you like to *permanently enable* Secure Boot on the USB armory? (y/N): y

Would you like to use F-Secure signed releases, enabling Secure Boot on the USB armory with permanent fusing of F-Secure public keys? (y/N): y

*** Armory Drive Programming Utility ***
***          READ CAREFULLY           ***
```

This will provision F-Secure signed Armory Drive firmware on your USB armory. By doing so, secure boot will be activated on the USB armory with permanent OTP fusing of F-Secure public secure boot keys.

Fusing OTP's is an ****irreversible**** action that permanently fuses values on the device. This means that your USB armory will be able to only execute F-Secure signed Armory Drive firmware after programming is completed.

In other words your USB armory will stop acting as a generic purpose device and will be converted to ***exclusive use of F-Secure signed Armory Drive releases***.

Armory Drive - device verification of previous checkpoint

```
imx, csf, proof, err := extract(buf)

if err != nil {
    return fmt.Errorf("could not extract archive, %v", err)
}

if len(proof) > 0 {
    var pb *api.ProofBundle

    pb, err = verifyProof(imx, csf, proof, keyring Conf.ProofBundle)

    if err != nil {
        err = fmt.Errorf("could not verify proof, %v", err)
        return
    }

    keyring Conf.ProofBundle = pb
    keyring Save()
}

// append HAB signature
imx = append(imx, csf...)

if err = usbarmory.MMC.WriteBlocks(2, imx); err != nil {
    return fmt.Errorf("could not write to MMC, %v", err)
}

log.Println("firmware update complete")
```

To ensure the firmware is valid, clients must verify that it is present in the transparency log. The **inclusion verification is performed by both the Armory Drive installer and the Armory Drive firmware** itself.

The installer can check the presence of the relevant hash directly against the published log.

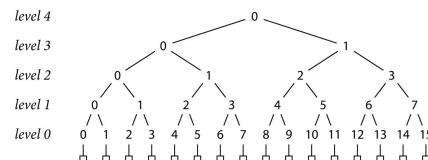

The firmware, not having network access, is unable verify the inclusion directly with the log but instead does so via a *proof bundle* passed from the installer.

This *proof bundle* contains a new checkpoint covering the new firmware release, the firmware manifest, and all the leaf hashes from the log (i.e. HASH_1, HASH_2, ..., etc.).

The presence of the leaf hashes allows the firmware to prove to itself that the checkpoint provided when the currently-running firmware was installed is consistent with (i.e. an ancestor of) the new one, ensuring that the tree history has not been compromised.

Transparency works if:

- There is a log at the centre which offers efficient cryptographically verifiable proofs of inclusion and append-only operation.
- Anyone preparing to rely on an artefact checks that it is present in the log before doing so (i.e. artefacts must be present in a log before anyone will trust them).
- There are one or more entities who are able to *verify* the correctness of artefacts in the log (i.e. "bad" artefacts will be spotted).
- Everyone listed above sees the same list of entries in the log.

A witness is an entity that:

- Verifies append-only operation of one or more logs, countersigning checkpoints if and only if the witness is convinced that a given checkpoint is consistent with all checkpoints previously issued by the same log.
- Makes these countersigned checkpoints publicly available.
- **Ensures there is only one view of the log.**

"In addition to verification done by the go command, third-party auditors can hold the checksum database accountable by iterating over the log looking for bad entries. **They can work together and gossip about the state of the tree as it grows to ensure that it remains uncompromised**, and we hope that the Go community will run them."

<https://go.dev/blog/module-mirror-launch/>

Building a hardware witness

The key goal is to build a device for *custodians* to:

- Help transparency-enabled ecosystems to further tighten their security properties (Go's sum DB, Sigstore, Pixel BT, LVFS, SigSum, Amory Drive).
- Allow low-touch and maintenance-free operation.
- Demonstrate and promote how to apply firmware transparency.

Device goals:

- Full transparency, open hardware and software.
- Reduced attack surface.
- Plug-and-go.

Combining our skills and projects:

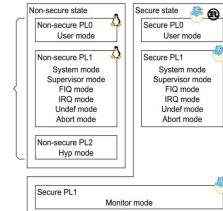

USB armory

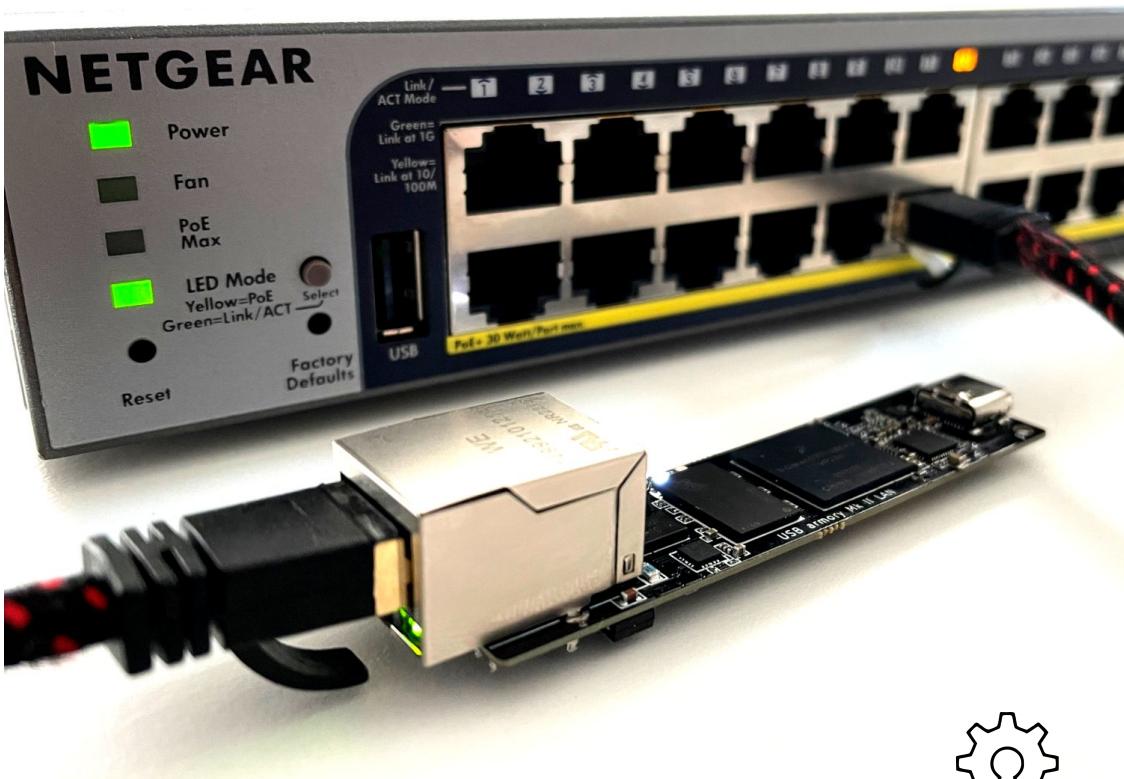

TamaGo

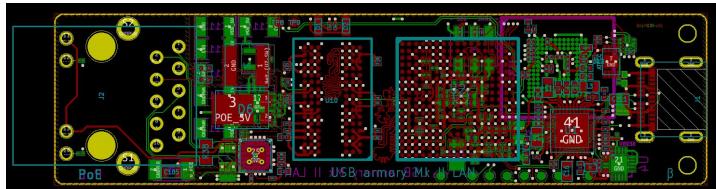

GoTEE

USB armory Mk II LAN

<https://github.com/usbarmory/usbarmory/wiki/Mk-II-LAN>

A new bespoke variant created specifically for the Armored Witness project.

- RAM: 512 MB or 1 GB DDR3
- Internal storage: 16 GB eMMC
- External secure element: NXP SE050
- SoC: NXP i.MX6UL/i.MX6ULL
(ARM® Cortex™-A7 528/900 MHz)
- Ethernet: 10/100-Mbps with IEEE 802.3af Power over Ethernet
- USB 2.0 over USB-C: DRP plug

It can be powered by either USB or PoE, acts as USB host or device depending on power mode.

Provides the same security features of the USB only model, full OSS tooling (no NXP blobs).

Hardware security features

High Assurance Boot (HAB)

SoC Boot ROM authentication of initial bootloader (i.e. Secure Boot).

CAAM (i.MX6UL) / DCP+RNGB (i.MX6ULZ)

SoC cryptographic accelerators and TRNG.

Secure Non-Volatile Storage (SNVS)

Encrypted storage of arbitrary data using unique keys,
voltage, temperature, clock tamper sensors.

Bus Encryption Engine (BEE)

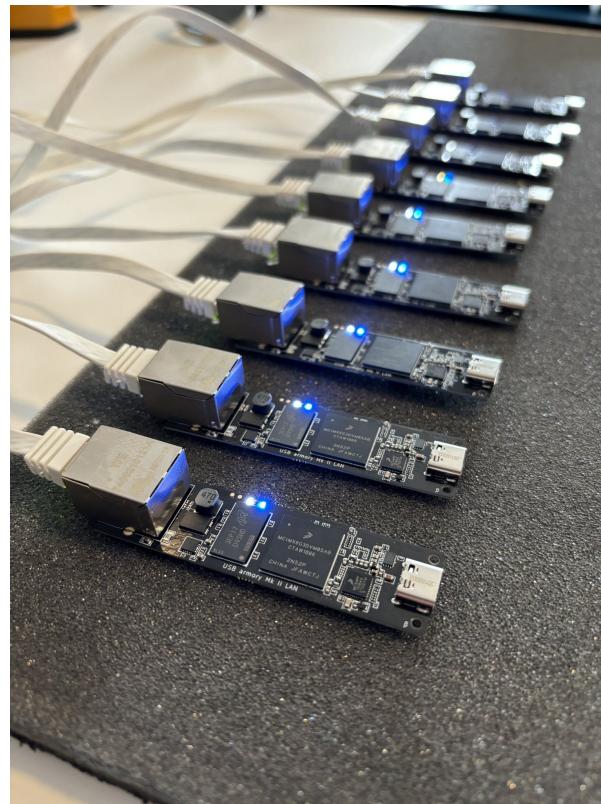

On i.MX6UL SoC it provides on-the-fly (OTF)
AES-128-CTR RAM encryption/decryption.

NXP SE050

External SE with hardware acceleration for elliptic-curve
cryptography as well as hardware based key storage.

Replay Protected Memory Block (RPMB)

The internal eMMC allows replay protected authenticated
access to flash memory partition areas, using a shared secret
between the host and the eMMC.

When security matters software and hardware optimizations matter less.

This means that less constrained hardware (e.g. SoCs in favor of MCUs) and higher level code are perfectly acceptable.

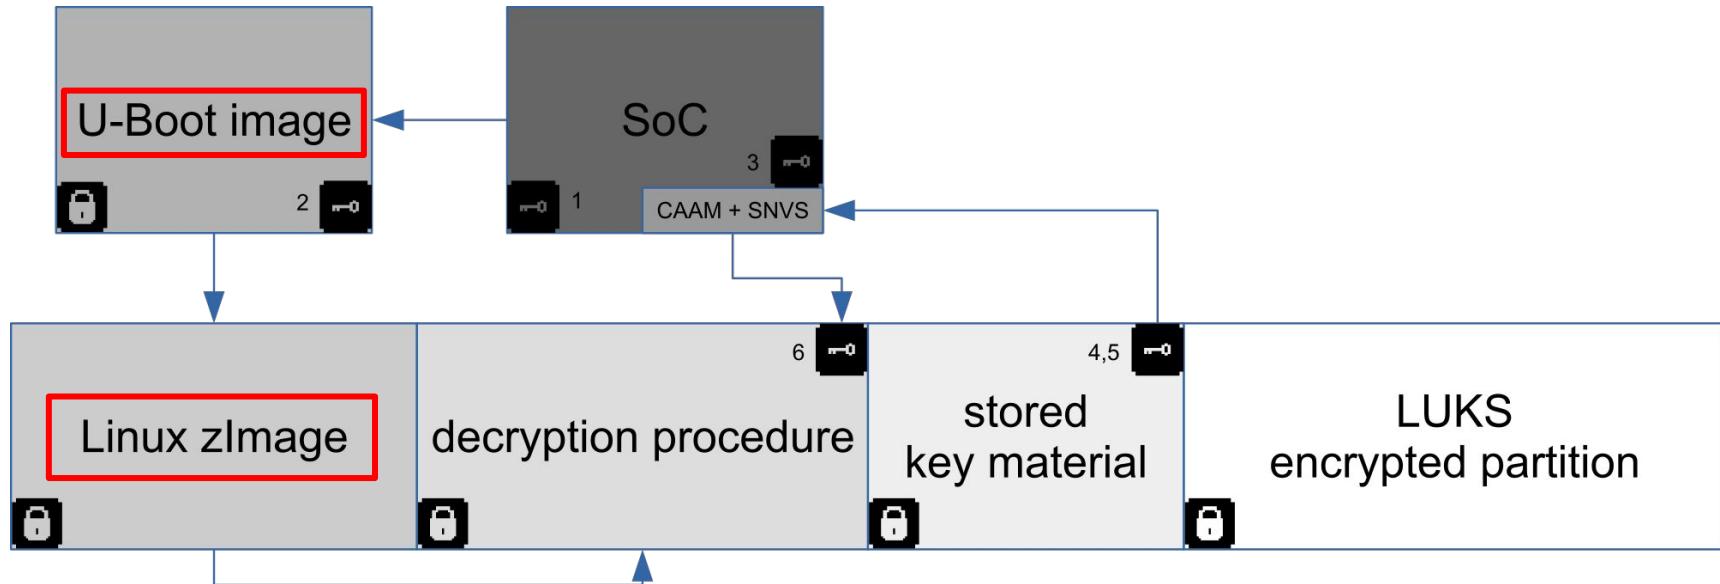

However high level programming typically entails several layers (e.g. OS, libraries) to serve runtime execution.

TamaGo spawns from the desire of **reducing the attack surface** of embedded systems firmware by **removing any runtime dependency on C code and inherently complex Operating Systems**.

In other words we want to **avoid shifting complexity around** and run a **higher level language**, such as Go in our effort, **directly on the bare metal**.

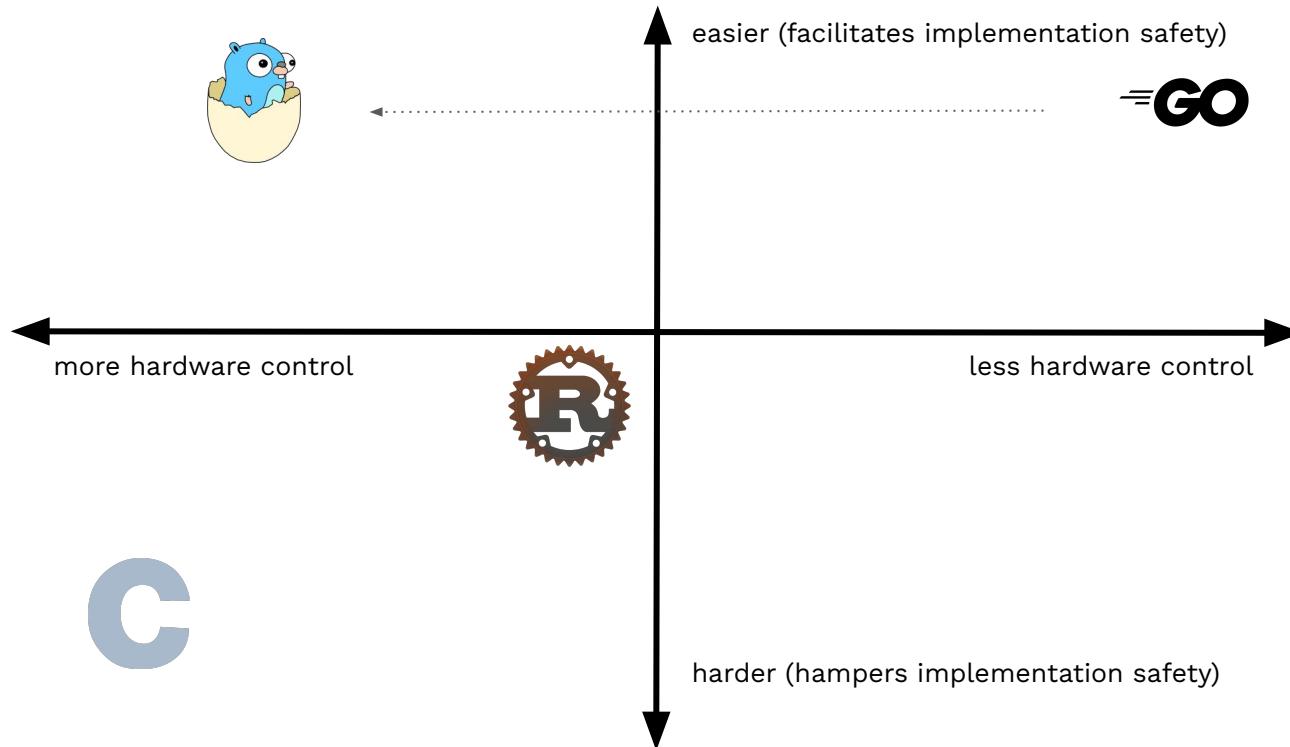

Reducing the attack surface

Typical secure booted firmware with authentication and confidentiality on an NXP i.M6UL.

Speed vs Safety

Disclaimer: chart presented for discussion and not to claim that language X is better than language Y, also scale is subjective.

Unikernels¹ are a single address space image to execute a “library operating system”, typically running under bare metal.

The focus is reducing the attack surface, carrying only strictly necessary code.

“True” unikernels are mostly unicorns, as a good chunk of available ones do not fit in this category and represent “fat” unikernels running under hypervisors and/or other (mini) OSes. And just shift around complexity (e.g. the app is PID 1).

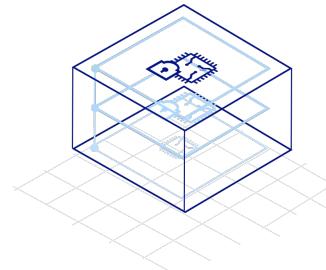

Apart from some exceptions there is always still a lot of C/dependencies involved in the underlying OS, drivers or hypervisor.

Running or importing *BSD kernels

Rump kernels (NetBSD based)
OSv (re-uses code from FreeBSD)

Running under hypervisor and 3rd party kernel

MirageOS (Solo5)
ClickOS (MiniOS)

Running under hypervisor

Nanos (Xen/KVM/Qemu) HalVM (Haskell, Xen)
LING (Erlang, Xen) RustyHermit (KVM)

Bare metal

GRISP (Erlang)
IncludeOS

¹ <https://en.wikipedia.org/wiki/Unikernel>

TamaGo in a nutshell

TamaGo is made of two main components.

- A **minimally¹** patched Go distribution to enable GOOS=tamago support, which provides freestanding execution on GOARCH=arm and GOARCH=riscv64 bare metal.
- A set of packages² to provide board support (e.g. hardware initialization and drivers).

TamaGo currently provides drivers for SoC families
NXP i.MX6UL (USB armory Mk II), BCM2835
(Raspberry Pi Zero, Pi 1, Pi 2) and SiFive FU540.

On the i.MX6UL we target development of security applications, TamaGo is fully integrated with our existing open source tooling for i.MX6 Secure Boot (HAB) image signing.

TamaGo also provides full hardware initialization removing the need for intermediate bootloaders.

¹ <https://github.com/usbarmory/tamago-go>

² <https://github.com/usbarmory/tamago>

TamaGo not only proves that it is possible to have a bare metal Go runtime, but does so with **clean and minimal modifications against the original Go distribution**².

Much of the effort has been placed to understand whether Go bare metal support can be achieved without complex re-implementation of memory allocation, threading, ASM/C OS primitives that would “pollute” the Go runtime to unacceptable levels.

Less is more. Complexity is the enemy of verifiability.

The acceptance of this (and similar) efforts hinges on maintainability, ease of review, clarity, simplicity and **trust**.

- ★ Designed to achieve upstream inclusion and with commitment to always sync to latest Go release.
- ★ ~4500 LOC of changes against Go distribution with clean separation from other GOOS support.
- ★ Strong emphasis on code reuse from existing architectures of standard Go runtime, see [Internals](#)¹.
- ★ Requires only one import (“library OS”) on the target Go application.
- ★ Supports unencumbered Go applications with nearly full runtime availability.
- ★ In addition to the compiler, aims to provide a complete set of peripheral drivers for SoCs.

¹ <https://github.com/usbarmory/tamago/wiki/Internals>

² Which by the way is self-hosted and has reproducible builds.

Go low level access

```
func (hw *BEE) Init() {
    hw.mu.Lock()
    defer hw.mu.Unlock()

    hw.ctrl = hw.Base + BEE_CTRL
    hw.addr0 = hw.Base + BEE_ADDR_OFFSET0
    hw.addr1 = hw.Base + BEE_ADDR_OFFSET1
    hw.key = hw.Base + BEE_AES_KEY0_W0
    hw.nonce = hw.Base + BEE_AES_KEY1_W0

    // enable clock
    reg.Set(hw.ctrl, CTRL_CLK_EN)
    // disable reset
    reg.Set(hw.ctrl, CTRL_SFTRST_N)

    // disable
    reg.Clear(hw.ctrl, CTRL_BEE_ENABLE)
}

func (hw *BEE) generateKey() (err error) {
    // avoid key exposure to external RAM
    key, err := dma.NewRegion(uint(hw.key), aes.BlockSize, false)

    if err != nil {
        return
    }

    addr, buf := key.Reserve(aes.BlockSize, 0)

    if n, err := rand.Read(buf); n != aes.BlockSize || err != nil {
        return errors.New("could not set random key")
    }

    if addr != uint(hw.key) {
        return errors.New("invalid key address")
    }

    return
}
```

Example: BEE initialization

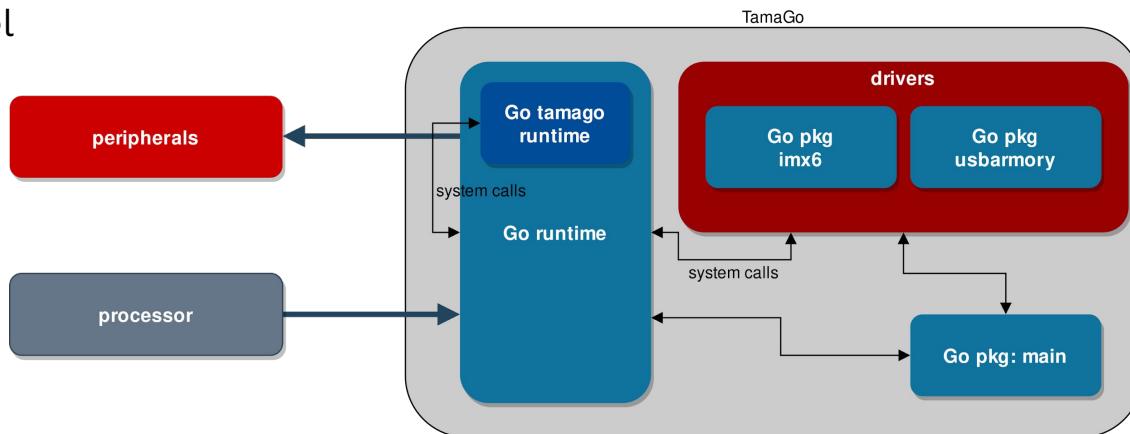

Go's `unsafe` can be easily identified to spot areas that require care (e.g. pointer arithmetic), it is currently used only in register and DMA memory manipulation primitives.

There are overall only 3 occurrences of `unsafe` used in `dma` and `reg` packages.

Applications are never required to use any `unsafe` function.

TamaGo unikernel

Developing, building and running

The full Go runtime is supported¹ without any specific changes required on the application side (Rust on bare metal², for comparison, requires `#![no_std]` pragma).

```
package main

import (
    _ "github.com/usbarmory/tamago/board/usbarmory/mk2"
)

func main() {
    // your code
}
```

```
GO_EXTLINK_ENABLED=0 CGO_ENABLED=0 GOOS=tamago GOARM=7 GOARCH=arm \
${TAMAGO} build -ldflags "-T 0x80010000 -E _rt0_arm_tamago -R 0x1000"
```

All Go ecosystem features in terms of build reproducibility, dependency management, profiling, debugging, remain intact.

Firmware can be compiled just as easily on Linux, Windows, macOS.

¹ <https://github.com/usbarmory/tamago/wiki/Import-report>

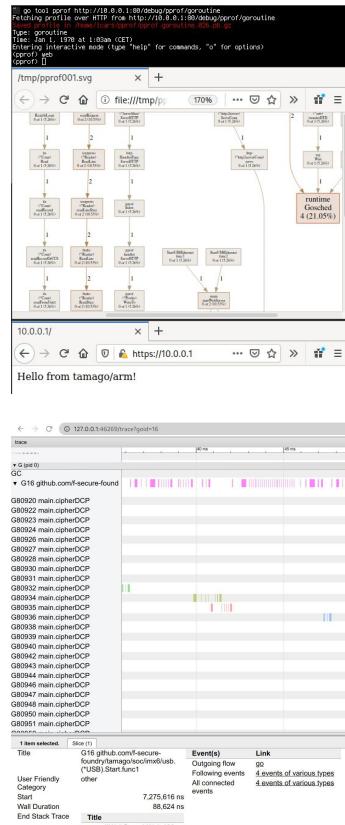

² <https://rust-embedded.github.io/book/intro/no-std.html>

1. The application requires a single import for the board package to enable necessary initializations.
2. Go code can be written with very few limitations and the SoC package exposes driver APIs.
3. go build can be used as usual (reproducible builds!) with few linker flags to define entry point.
4. The SoC package supports native loading (no bootloader required!).

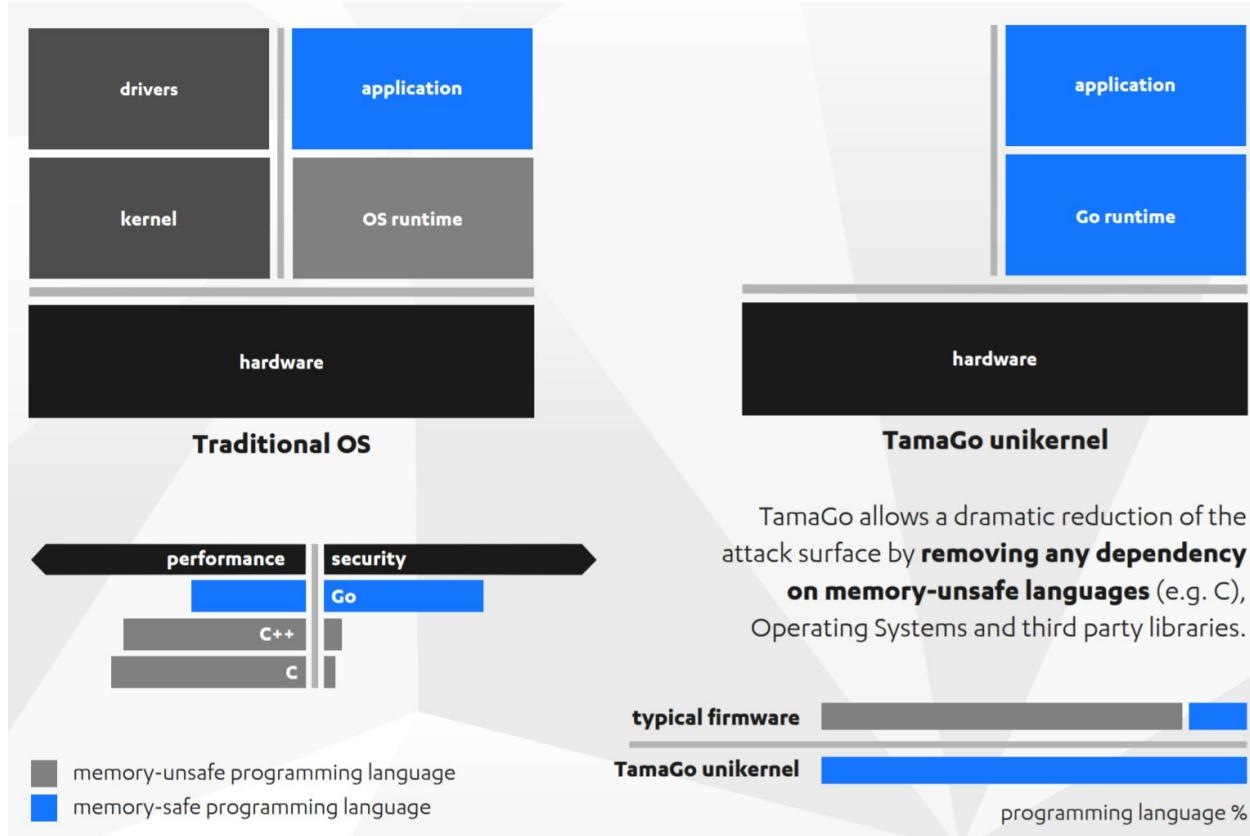

Reducing the attack surface

Block	LOCs	Driver support
ARM	900	CPU MMU, timer, exceptions, IRQ handling
BEE	130	OTF AES RAM encryption/decryption
CAAM	840	accel. AES/ECC/CMAC/SHA/TRNG, HUK derivation
DCP	400	accel. AES/SHA, HUK derivation
ENET	370	10/100-Mbps Ethernet driver, MII support
RNGB	70	True Random Number Generator
RPMB	230	Replay Protected Memory Block
SNVS	180	tamper proof sensors
USB	1200	USB 2.0 in device mode
USDHC	1100	eMMC (up to HS200 speed) / SD (up to SDR104 speed)
MK2	680	USB armory Mk II board support package

The TamaGo firmware allows creation of true unikernels, incorporating in a single binary boot code, peripheral drivers, libraries and application code with Minimal dependencies and all the benefits of the full Go ecosystem, including debugging.

Improving memory safety

GoKey - The bare metal Go smart card

The GoKey application implements a composite USB OpenPGP 3.4 smartcard and FIDO U2F token, written in pure Go (~2500¹ LOC).

It allows to implement a radically different security model for smartcards, taking advantage of TamaGo to safely mix layers and protocols not easy to combine.

For instance authentication can happen over SSH instead of plaintext PIN transmission over USB.

	Trust anchor	Data protection	Runtime	Application	Requires tamper proofing	Encryption at rest
traditional smartcard	flash protection	flash protection	JCOP	JCOP applets	Yes	No
USB armory with GoKey	secure boot	SoC security element	TamaGo	Go application	No	Yes

<https://github.com/usbarmory/gokey>

armory-boot - USB armory boot loader

A primary signed boot loader (~300 LOC) to launch authenticated Linux kernel images on secure booted¹ USB armory boards, replacing U-Boot.

```
func boot(kernel []byte, dtb []byte, cmdline string) {
    dma.Init(dmaStart, dmaSize)
    mem, _ := dma.Reserve(dmaSize, 0)

    dma.Write(mem, kernel, kernelOffset)
    dma.Write(mem, dtb, dtbOffset)

    image := mem + kernelOffset
    params := mem + dtbOffset

    arm.ExceptionHandler = func(n int) {
        if n != arm.SUPERVISOR {
            panic("unhandled exception")
        }
    }

    usbarmory.LED("blue", false)
    usbarmory.LED("white", false)

    imx6ul.ARM.DisableInterrupts()
    imx6ul.ARM.FlushDataCache()
    imx6ul.ARM.Disable()

    exec(image, params)
}

svc()
}
```

```
func verifySignature(buf []byte, s []byte) (valid bool, err error) {
    sig, err := DecodeSignature(string(s))

    if err != nil {
        return false, fmt.Errorf("invalid signature, %v", err)
    }

    pub, err := NewPublicKey(PublicKeyStr)

    if err != nil {
        return false, fmt.Errorf("invalid public key, %v", err)
    }

    return pub.Verify(buf, sig)
}

func verifyHash(buf []byte, s string) bool {
    // use hardware acceleration
    sum, _ := imx6ul.DCP.Sum256(buf)

    if hash, err := hex.DecodeString(s); err != nil {
        return false
    }

    return bytes.Equal(sum[:], hash)
}
```

GoTEE - Trusted Execution Environment

The GoTEE framework implements concurrent instantiation of TamaGo based unikernels in privileged and unprivileged modes, interacting with each other through monitor mode and custom system calls.

With these capabilities GoTEE implements a pure Go Trusted Execution Environment (TEE) bringing Go memory safety, convenience and capabilities to bare metal execution within TrustZone Secure World.

It supports any freestanding user mode applets (e.g. TamaGo, C, Rust) and any “rich” OS running in NonSecure World (e.g. Linux).

GoTEE in the wild: space!

On May 22nd 2023 (UTC 05:00:32) the USB armory Mk II got a lift to space!

On February 27th 2024 (UTC 07:27:00) the same unit went back to space.

GoTEE supervised a TamaGo based unikernel (acting as Trusted Applet) and a full Linux instance isolated in NonSecure World to test Post Quantum Key exchanges.

For this occasion TamaGo and GoTEE have been updated with full watchdog and interrupt support.

The payload remained operation for the entire flight duration performing exactly 400 PQC key exchanges. As far as we know this is the first time bare metal Go executed in space.

Andrea Barisani
@AndreaBarisani

...

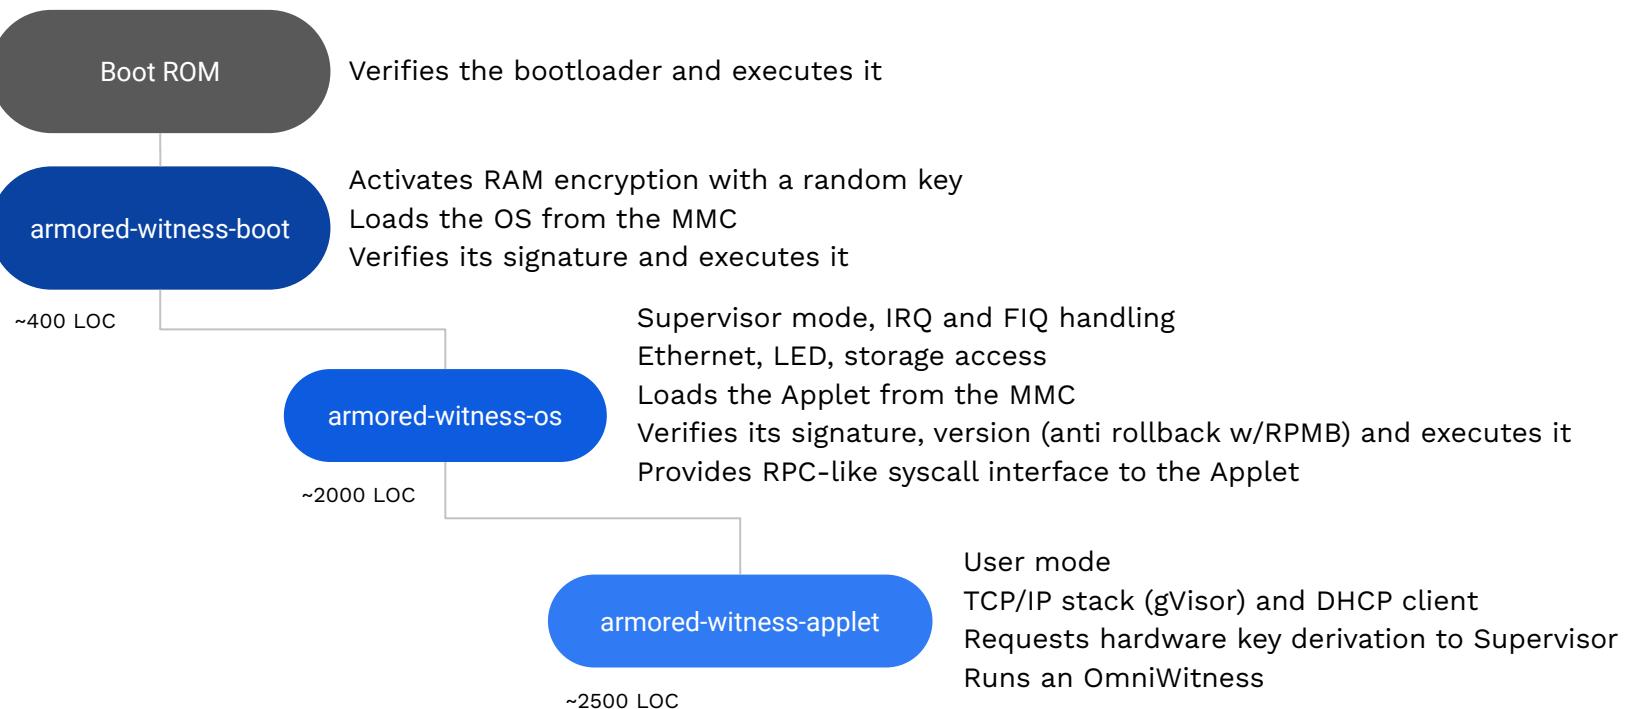

Yesterday (UTC 05:00:32) @WithSecure USB armory got a lift (~225 km apogee) from the MAPHEUS-13 rocket launched from the Esrange Space Center.

Thanks to @DLR_de @adesso_SE for this amazing collaboration!

Our bare metal GoTEE performed Post Quantum key exchange in space!

Building a hardware witness

All firmware verification past the Boot ROM stage verify, through FT proof bundles, the presence of one or more trusted signatures (multi party signing) on the release manifest. The release manifest includes the binary hash, log checkpoint, the index of the manifest in the log and its corresponding inclusion proof.

The OS and Applet must be published on the log to be usable on the device.

<https://github.com/transparency-dev/armored-witness>

Minimising trust

All firmware is open source, written in TamaGo, and is build-reproducible by anyone. All firmware is logged to a Firmware Transparency log at build and release time.

The provision tool will only use firmware artefacts discovered in the FT log in order to program devices. The on-device self-update process requires that updated firmware is hosted in the FT log.

The verify tool can be used by *custodians* to inspect the device, extract the firmware components from it, and verify that they are present in the FT log.

The verify_build command continuously monitors the contents of the FT log, and tests that every logged firmware is indeed reproducibly built.

Google and WithSecure are able to quickly become aware of misuse of their signing identities to release unauthorised firmware updates.

Anyone can verify that each firmware can be rebuilt consistently with what is running, logged and its source.

}
```

Code snippet - Trusted OS IRQ/syscall handling

```
func handler(ctx *monitor.ExecCtx) (err error) {
    switch ctx.ExceptionVector {
    case arm.FIQ:
        // service Ethernet IRQs for incoming packets
        return fiqHandler(ctx)
    case arm.SUPERVISOR:
        // service system calls
        switch ctx.A0() {
        case syscall.SYS_WRITE:
            return bufferedStdoutLog(byte(ctx.A1()))
        case RX:
            return rxFromApplet(ctx)
        case TX:
            imx6ul.WDOG2.Service(watchdogTimeout)
            return txFromApplet(ctx)
        case FIQ:
            // re-activate Fast Interrupts
            bits.Clear(&ctx.SPSR, CPSR_FIQ)
        case FREQ:
            return imx6ul.SetARMFreq(uint32(ctx.A1()))
        default:
            // handle RPC
            return monitor.SecureHandler(ctx)
        }
    default:
        log.Fatalf("unhandled exception %x", ctx.ExceptionVector)
    }

    return
}
```

https://github.com/transparency-dev/armored-witness-os/blob/main/trusted_os/handler.go

```
func eventHandler() {
    var handler rpc.Handler

    handler.G, handler.P = runtime.GetG()

    if err := syscall.Call("RPC.Register", handler, nil); err != nil {
        log.Fatalf("TA event handler registration error, %v", err)
    }

    n := 0
    out := make([]byte, enet.MTU)

    for {
        // To avoid losing interrupts, re-enabling must happen only
        // after we are sleeping.
        go syscall.Write(FIQ, nil, 0)

        // sleep indefinitely until woken up by runtime.WakeG
        time.Sleep(math.MaxInt64)

        // check for Ethernet RX event
        for n = rxFromEth(out); n > 0; n = rxFromEth(out) {
            rx(out[0:n])
        }
    }
}
```

https://github.com/transparency-dev/armored-witness-applet/blob/main/trusted_applet/handler.go

Putting it all together

The applet observes public transparency logs verifying that they're operating in an append-only fashion, and counter-signing those checkpoints which it has determined are consistent with all previous checkpoints its seen from the same log.

The counter-signed checkpoints are sent to a **distributor**, which then collates counter-signatures for a given checkpoint from one or more Armored Witness devices, and serves them via a public API.

The benefit of this system comes through **removing trust from log operators** to behave honestly, and **placing some of that trust in the witnesses**.

Splitting the trust across multiple parties in this way means that **a larger number of parties must collude to hide malfeasance**, and as other witness implementations/networks start to appear, the number of parties required to collude increases correspondingly.

However, **we can minimise the amount of trust required** to be placed in the Armored Witness by having it be **as transparent as possible** too.

<https://github.com/transparency-dev/armored-witness>
